

## Substance Information Document

### Benzyl carbinol

#### 1. Substance identity

Name	Benzyl carbinol
Synonyms	2-Phenethyl alcohol; Phenylethyl alcohol; 2-Phenylethanol; 2-Phenylethyl alcohol; 2-Phenylethan-1-ol; $\beta$ -Phenylethanol;
IUPAC Name	2-phenylethanol
CAS	60-12-8

#### 2. Toxicological information

Genotoxicological tests with 2-phenethyl alcohol were all negative. Intraperitoneal injections of 2-phenethyl alcohol at 100 mg/kg bw revealed an increase in cellular proliferation in the lung alveoli, however, this could not be confirmed in a later experiment. Generally, 2-phenethyl alcohol is considered as non-skin irritating by experts' groups. However, skin irritation was detected in a few volunteers after patch tests. Low levels of erythema and desquamation were observed in rats after undiluted 2-phenethyl alcohol at 70 mg/kg bw/day and above was topically applied, doses at 140 mg/kg bw/day caused reduction in foetal body weight and delay in ossification, hence, the developmental NOAEL was reported as 70 mg/kg bw/day. After 2-phenethyl alcohol oral gavage administration to rabbits, a developmental NOAEL of 50 mg/kg bw/day was determined based on foetal body weight decrease in males and females and skeletal variations and malformations. In a rat reproductive toxicological study, the NOAEL for 2-phenethyl alcohol applied by oral gavage was 4.3 mg/kg bw/day, based on foetal malformations and reduced live litter size at the higher doses.

0.5% to 0.75% solutions of 2-phenethyl alcohol were reported to irritate the human eye. Eye irritation was also detected in rabbits using solutions of 1% to 15%.

2-phenethyl alcohol has low toxicity based on results from an acute rat inhalation study receiving a nominal concentration of 4.63 mg/L. Reported LD<sub>50</sub> values indicate a low-moderate order of acute oral toxicity (rats: 1500 mg/kg bw to 1609 mg/kg bw, mice: 800-1500 mg/kg bw, guinea pigs: 400-2540 mg/kg bw).

Based on limited data, 2-phenylethyl alcohol has low toxicity following repeated oral exposure. No adverse effects were reported when rats were fed diets containing 2-phenethyl alcohol providing 62.5-2000 mg/kg bw/day for 14 days. Oral gavage administration in rabbits at 300 mg/kg bw/day caused, however, severe toxic effects, including no food consumption and marked body weight loss. In this study a maternal NOAEL of 43 mg/kg bw/day was established.

Based on the results from a 90-day study in rats, 2-phenethyl alcohol has low toxicity following repeated dermal exposure (NOAEL= 510 mg/kg bw/day).

JECFA and EFSA concluded that the use of 2-phenethyl alcohol as a food flavouring is of “no safety concern” at then-current estimated intakes of 1200-1400 and 330 µg/person/day in Europe and the US, respectively.

### 3. Addictiveness and attractiveness

Inhalation of 2-phenethyl alcohol prolonged the pentobarbital-induced sleep time in mice. 20 minutes after a 15-minute inhalation of an unspecified concentration of 2-phenethyl alcohol, anxiety-like behaviour in mice was reported to be increased and depression-like behaviour was decreased. While another study in mice exposed to 2-phenethyl alcohol “odours” (filter paper soaked in the material) for 5 minutes showed anxiolytic effects, as confirmed by low blood corticosterone levels.

Solutions of 2-Phenethyl alcohol that were allowed to vaporize and pervade the cage via natural diffusion for 1 hour, demonstrated sedative effects in mice (reduction in spontaneous motor activity). Narcosis occurred within 1-5 minutes after mice were given single oral gavage dose of 1-2 g/kg bw, and performances of mice on a tilting plane were highly reduced 15 minutes after the administration of a single oral dose of 300, 600 or 900 mg phenethyl alcohol/kg bw.

2-Phenethyl alcohol local anaesthetic properties in mice were shown to be related to “a reduction in dipole potential and microviscosity of hippocampal membranes, with a concomitant increase in lateral diffusion”. The effects appear to be mediated via the hippocampal serotonin 1A receptor.
