

Toxicological profile for gamma-Hexalactone

This ingredient has been assessed to determine potential human health effects for the consumer. It was considered not to increase the inherent toxicity of the product and thus is acceptable under conditions of intended use.

1. Name of substance and physico-chemical properties

1.1. IUPAC systematic name

5-Ethyloxolan-2-one (PubChem)

1.2. Synonyms

.gamma.-Ethyl-.gamma.-butyrolactone; .gamma.-Ethyl-n-butyrolactone; .gamma.-Ethylbutyrolactone; .gamma.-Hexalactone; .gamma.-Hexanolactone; .GAMMA.-LACTONE; 2(3H)-Furanone, 5-ethyldihydro-; 4-Ethyl-4-butanolide; 4-Ethyl-4-hydroxybutanoic acid lactone; 4-Ethylbutanolide; 4-ethylbutanolide (gamma-hexalactone); 4-Hexanolide; 4-hydroxy-Hexanoate; 4-hydroxy-Hexanoic acid gamma-lactone; 4-hydroxy-Hexanoic acid lactone; 4-Hydroxyhexanoate; 4-Hydroxyhexanoic acid lactone; 5-Ethyl-dihydro-furan-2-one; 5-ethyloxolan-2-one; 5-Ethyltetrahydro-2-furanone; 6-Caprolactone; AKOS015908187; EINECS 211-778-8; FEMA No. 2556; Frutinal; gamma -Caprolactone; Gamma Hexalactone; gamma-Caprolactone; gamma-Hexanolactone; hexa-4-olide; Hexan-4-olide; Hexanoic acid, 4-hydroxy-, gamma-lactone; Hexanoic acid, 4-hydroxy-, lactone; Hexanolide-1,4; UNII-J16NAT1G41; (PubChem)

1.3. Molecular formula

C₆H₁₀O₂ (PubChem)

1.4. Structural Formula

(PubChem)

1.5. Molecular weight (g/mol)

114.14(PubChem)

1.6. CAS registration number

695-06-7

1.7. Properties

1.7.1. Melting point

(°C): -18 (ChemSpider; EPISuite, 2017)

1.7.2. Boiling point

(°C): 215.5 (EPISuite, 2017); 218-219 (ChemSpider)

1.7.3. Solubility

32190 mg/L at 25°C (estimated) (EPISuite, 2017)

1.7.4. pKa

No data available to us at this time.

1.7.5. Flashpoint

(°C): 79.3 or 98 (ChemSpider)

1.7.6. Flammability limits (vol/vol%)

No data available to us at this time.

1.7.7. (Auto)ignition temperature

(°C): No data available to us at this time.

1.7.8. Decomposition temperature

(°C): No data available to us at this time.

1.7.9. Stability

No data available to us at this time.

1.7.10. Vapor pressure

0.165 mmHg at 25°C (estimated) (EPISuite, 2017); 0.2±0.4 mmHg at 25°C (estimated) (ChemSpider)

1.7.11. log Kow

1.037 (ChemSpider)

2. General information

2.1. Exposure

OTHER SOURCES OF EXPOSURE			
Cosmetics	Yes (CosIng)	Food	Yes (Burdock, 2010).

Environment	No evidence	Pharmaceuticals	No evidence
-------------	-------------	-----------------	-------------

gamma-Caprolactone (CAS RN 695-06-7) is used as a fragrance and perfuming agent in cosmetics in the EU. As taken from CosIng (undated).

The following uses are reported in the USA:

Food category	Usual (ppm)	Max (ppm)
Alcoholic beverages	0.1	0.3
Baked goods	24.5	31.18
Frozen dairy	19.89	24.6
Gelatins, puddings	22.19	30.23
Hard candies	4.92	4.92
Nonalcoholic beverages	6.64	10.92
Soft candy	22.59	32.55

Estimated intake from use as flavourings in the USA: 0.0002966 mg/kg bw/day.

As taken from Burdock, 2010.

Maximised Survey-derived Daily Intakes (MSDI-EU): 160 µg/capita/day.

As taken from EFSA, 2005.

gamma-Hexalactone (CAS RN 695-06-7) is listed as a fragrance ingredient by IFRA and on the US EPA's InertFinder Database.

gamma-Caprolactone (CAS RN 695-06-7) is listed as an ingredient in inside the home products by the CPID.

gamma-Hexalactone (CAS RN 695-06-7) is used as a flavour enhancer in non-medicinal natural health products (Health Canada, 2021).

2.2. Combustion products

This ingredient was investigated in a pyrolysis study. Results are given in Baker and Bishop (2004) J. Anal. Appl. Pyrolysis, 71: 223-311.

Ingredients CAS Number	Chemical Class	Mol. Wt. (M) Bp or Mp (°C)	Max cig Appln. Level (ppm)	Purity of sample pyrolysed (%)	Composition of pyrolysate (Compound %)	Max level in smoke (µg)
g- Hexalactone 695-06-7	g- Lactone	M=114 bp 100- 102 at 18 mmHg	10	98	g-Hexalactone 99.6 Methylethylperhydro­ furanone? 0.2 Caprolactone? 0.2	5 0.01 0.01

2.3. Ingredient(s) from which it originates

Gamma-hexalactone has been detected in the urine of normal human adults (Zlatkis & Liebich, 1971).

As taken from EFSA, 2005. gamma-Hexalactone is formed by the reduction of sorbic acid using Zn, Sn or SnCl₂ and concentrated HCl in acetic acid solution at 85°C; from ethylene oxide and sodium malonic ester, also from propyl alcohol and methylacrylate in the presence of di-tert-butyl peroxide.

“Reported found in apple juice, apricot, orange juice, guava, raisin, papaya, peach, pineapple, berries, asparagus, peas, potato, tomato, breads, cheeses, butter, milk, chicken fat, cooked beef, cooked pork, beer, cognac, grape wines, cocoa, tea, filberts, pecans, passion fruit, Japanese plum, beans, mushroom, starfruit, mango, dried fig, prickly pear, licorice, soursop, Cape gooseberry, nectarines, quince, pawpaw and other sources”.

As taken from Burdock, 2010.

Gamma-lactones contribute to the aroma of butter and various fruits(1). gamma-Hexalactone naturally occurs in fruits such as passion fruit, plums, tomatoes, etc.

As taken from WHO Food Additive Series 40: Aliphatic lactones. Prepared by The forty-ninth meeting of the Joint FAO/WHO Expert Committee on Food Additives (JECFA), 1998. Main natural food occurrence

Food	mg/kg
raspberry	0.005-1
other fruits	up to 0.06
asparagus (cooked)	trace
beer	0.02
pork heated	trace-0.1

3. Status in legislation and other official guidance

As a food flavouring additive, the material has been assessed under the provisions of the Federal Food, Drug and Cosmetic Act, section 201 (s), by the Expert Committee of the USA Flavour and Extract manufacturer's Association (FEMA), to be generally recognized as safe (GRAS) under current conditions of use.

The Joint FAO/WHO Expert Committee on Food Additives has assessed gamma-hexalactone as presenting no safety concerns at current levels of intake when used as a flavouring agent. The daily per capita intake is estimated at 0.32 µg/kg bw/day in the USA and 3.10 µg/kg bw/day in Europe². It has also been defined as a flavouring substance which may be used as foodstuffs by the Council of Europe Committee of Experts on Flavouring Substances at an upper level of 5 mg/kg in foods. Safety evaluations of certain food additives and contaminants,

As taken from WHO Food Additive Series 40: Aliphatic lactones. Prepared by The forty-ninth meeting of the Joint FAO/WHO Expert Committee on Food Additives (JECFA), 1998. FEMA GRAS No. 2556 (Hall RL & Oser BL, 1965)

JECFA considered this substance to be of “no safety concern” as a food flavouring at the current estimated levels of intake of 190 µg/person/day in Europe and 19 µg/person/day in the US (JECFA, 1998).

gamma-Hexalactone (CAS RN 695-06-7) is included on the FDA's inventory of Substances Added to Food (formerly EAFUS) as a flavoring agent or adjuvant, and is permitted for direct addition to

food for human consumption under 21 CFR section 172.515 (Synthetic flavoring substances and adjuvants) (FDA, 2024).

There is a REACH dossier on hexan-4-olide (CAS RN 695-06-7) (ECHA).

Hexan-4-olide (CAS RN 695-06-7) is not classified for packaging and labelling under Regulation (EC) No. 1272/2008 (ECHA, 2024).

5-Ethyltetrahydro-2-furanone (CAS RN 695-06-7) is listed in the US EPA InertFinder Database as approved for food, non-food use and fragrance use pesticide products.

2(3H)-Furanone, 5-ethylidihydro- (CAS RN 695-06-7) is listed in the US EPA's Toxic Substances Control Act (TSCA) inventory and in 2024 CDR TSCA Inv Active list.

The TSCA inventory and 2024 CDR list.

gamma-Hexalactone (CAS RN 695-06-7) is included on the US EPA's list of Safer Chemical Ingredients (US EPA, 2024).

Hexano-1,4-lactone (CAS RN 695-06-7) is authorised for use as a flavouring substance in all categories of flavoured foods in the EU under Regulation No 872/2012 (European Commission, 2012).

CoE: No. 2254. Category A – may be used in food stuffs. Upper use levels: Beverages: 5 mg/kg; Food: 5 mg/kg.

As taken from CoE, 2000.

FL No	In register	Flavis name	CAS No	CE No	JECFA No	FEMA No	Chemical group number	Status	Remarks	Ref short
10.021	Yes	Hexano-1,4-lactone	695-06-7	2254	223	2556	09	No further evaluation needed	JECFA evaluated gamma-hexalactone (CASrn as in Register). Register CASrn refers to the racemate	JECFA, 1999b

As taken from Flavouring substances database (Flavis). **4. Metabolism/Pharmacokinetics**

4. Metabolism/Pharmacokinetics

4. Metabolism/Pharmacokinetics

4.1. Metabolism/metabolites

Linear saturated 5-hydroxycarboxylic acids (formed from delta-lactones) are converted, via acetyl coenzyme A, to hydroxythioesters which then undergo β -oxidation and cleavage to yield an acetyl CoA fragment and a new β -hydroxythioester reduced by 2 carbons. Even-numbered carbon acids continue to be oxidized and cleaved to yield acetyl CoA while odd-numbered carbon acids yield acetyl CoA and propionyl CoA. Acetyl CoA enters the citric acid cycle directly while propionyl CoA is transformed into succinyl CoA, which then enters the citric acid cycle (Voet & Voet, 1990). Linear

saturated 4- or 6-hydroxycarboxylic acids (formed from gamma- or epsilon-lactones including gamma-Hexalactone) participate in the same pathway; however, loss of an acetyl CoA fragment produces an alpha-hydroxythioester which undergoes alpha-oxidation and alpha-decarboxylation to yield a linear carboxylic acid and eventually carbon dioxide.

As taken from WHO Food Additive Series 40: Aliphatic lactones. Prepared by The forty-ninth meeting of the Joint FAO/WHO Expert Committee on Food Additives (JECFA), 1998.

Rat liver and human plasma γ -lactonase reversibly hydrolyzed γ -caprolactone. (Fishbein and Bessman, 1966).

Numerous chemical agents, including gamma-heptalactone, gamma-valerolactone, gamma-decalactone, delta-decalactone, gamma-dodecalactone, delta-undecalactone, and gamma-hexalactone, are mild to weak inhibitors of coumarin-7-hydroxylases (also known as CYP2A5 and CYP2A6; these are enzymes within the P450 enzyme system that metabolize compounds in the body). These 7 chemicals are among those found on the additives list. Because CYP2A6 is involved in the metabolism of nicotine, the presence of these chemicals could decrease smokers' metabolism of nicotine and maintain higher blood levels (thus increasing smokers' exposure to nicotine by slowing degradation of nicotine in the bloodstream). Furthermore, the inhibitory effect of these chemicals on CYP2A6, although relatively weak in isolation, might be greater when the chemicals act in combination. (Rabinof M et al., 2007).

4.2. Absorption, distribution and excretion

Analysis of the urine from 10 normal human adults revealed the presence of γ -caprolactone (Zlatkis and Liebich, 1971).

4.3. Interactions

"Paraoxonase 1 (PON1) is a high-density lipoprotein (HDL)-associated enzyme that by hydrolysing exogenous and endogenous substrates can provide protection against substrate induced toxicity. To investigate the extent to which PON1 provides protection against lactone induced DNA damage, DNA damage was measured in HepG2 cells using the neutral Comet assay following lactone treatment in the presence and absence of exogenous recombinant PON1 (rPON1). Low dose lactones (10 mM) caused little or no damage while high doses (100 mM) induced DNA damage in the following order of potency: α -angelica lactone > γ -butyrolactone ~ γ -hexalactone > γ -heptalactone ~ γ -octalactone ~ γ -furanone ~ γ -valerolactone > γ -decalactone. Co-incubation of 100 mM lactone with rPON1, resulted in almost all cells showing extensive DNA damage, particularly with those lactones that decreased rPON1 activity by > 25%. In contrast, with the lactones that are poor rPON1 substrates (γ -decalactone and γ -furanone), rPON1 did not increase DNA damage. DNA damage induced by a 1 h co-treatment with 10 mM α -angelica lactone and rPON1 was reduced when cells were incubated for a further 4 h in fresh medium suggesting break formation was due to induced DNA damage rather than apoptosis. Preincubation (1-6 h) of α -angelica lactone with rPON1 in the absence of cells, decreased cellular DNA damage by around 40% in comparison to cells treated without preincubation. These results suggest that in addition to its well-recognised detoxification effects, PON1 can increase genotoxicity potentially by hydrolysing certain lactones to reactive intermediates that increase DNA damage via the formation of DNA adducts." As taken from Shangula S et al. 2019. Arch. Toxicol. 93(7), 2035-2043. PubMed, 2020 available at <https://pubmed.ncbi.nlm.nih.gov/31209508/>

5. Toxicity

5.1. Single dose toxicity

Type of Test	Route of Exposure or Administration	Species/Test System	Dose Data	Toxic Effects	Reference
LD50	Oral	Rodent - rat	>5 gm/kg	Details of toxic effects not reported other than lethal dose value	FCTXAV Food and Cosmetics Toxicology. (London, UK) V.1-19, 1963-81. For publisher information, see FCTOD7. Volume(issue)/page/year: 17,794,1979
LD50	Administration onto the skin	Rodent - rabbit	>5 gm/kg	Details of toxic effects not reported other than lethal dose value	FCTXAV Food and Cosmetics Toxicology. (London, UK) V.1-19, 1963-81. For publisher information, see FCTOD7. Volume(issue)/page/year: 17,794,1979

As taken from RTECS, 1997

An LD50 of >5000 mg/kg bodyweight was determined after administration of gamma-hexalactone by gavage to rats Moreno, O.M. (1977b) Oral LD50 of gamma-heptalactone in rats. Unpublished report from MB Research Laboratories Inc. (Submitted to WHO by FEMA).

5.2. Repeated dose toxicity

No data available to us at this time.

5.3. Reproduction toxicity

Reproductive and developmental toxicity			
Species	Test conditions	Effects	Reference
<p>No data were identified on gamma-hexalactone.</p> <p>A JECFA publication reports briefly that there was no evidence of embryotoxicity or foetal malformations in a teratogenicity study where Sprague-Dawley rats were given gamma-butyrolactone at up to 500 mg/kg bw per day on days 6-15 of gestation (Kronevi et al. 1988). No further details given in JECFA, the administration route was probably gavage (JECFA, 1998).</p>			

In a developmental toxicity study (GLP and OECD 414-compliant) performed on CrI:CD (Sprague Dawley) IGS BR rats (25/sex/dose), γ -hexalactone was administered through oral gavage at dose levels of 0 (vehicle control: deionized water), 100, 300, or 1000 mg/kg/day for a period of 14 days during gestation from days 6–19. No treatment-related changes were reported for dams in clinical signs, body weights, gravid uterine weight, feed consumption, and necropsy examination. A significant decrease in fetal body weight was reported in the high-dose group; however, the decrease in body weight was within the historical control range. At 300 mg/kg/day, external malformations, including meningocele, were reported in 1 fetus; visceral malformations, including a malpositioned descending aorta, were reported in another fetus; and a skeletal malformation (a vertebral centra anomaly; the right half of lumbar centrum number 2 was absent, and the right half of lumbar centrum number 1 was malpositioned) was reported in 1 fetus. However, these changes were reported in only 3 of 365 fetuses examined at this dose level and were not present at any other dose level. Other soft tissues and skeletal malformations and variants were reported in a

single fetus, but they did not occur in a dose-related manner. In addition, the skeletal variants reported in all treated groups were within the historical control data and, therefore, not considered to be treatment-related. A conservative NOAEL for developmental toxicity was considered to be 300 mg/kg/day, based on a significant decrease in fetal body weight at 1000 mg/kg/day (ECHA, 2013).

Therefore, the γ -hexalactone MOE for the developmental toxicity endpoint can be calculated by dividing the γ -hexalactone NOAEL in mg/kg/day by the total systemic exposure to γ -hexalactone, 300/0.00058, or 517241.

In addition, the total systemic exposure to γ -hexalactone (0.58 μ g/kg/day) is below the TTC (9 μ g/kg/day; Kroes et al., 2007; Laufersweiler et al., 2012) for the developmental toxicity endpoint of a Cramer Class II material at the current level of use.

As taken from Api AM et. Al. Food and Chemical Toxicology (2022). Available at: <https://pubmed.ncbi.nlm.nih.gov/35817258/>

5.4. Mutagenicity

Genotoxicity	[+ve, positive; -ve, negative; ?, equivocal; with, with metabolic activation; without, without metabolic activation]				
In vivo					
Species	Test conditions		Endpoint	Result	Reference
No studies on gamma-hexalactone were identified. Several studies on structurally-related compounds are mentioned briefly below (see the Ingredient Profiles for further details).					
Mouse	STRUCTURALLY RELATED LACTONES No evidence of genotoxic potential was found in 4 studies on gamma-butyrolactone and 1 on gamma-undecalactone. These were four micronucleus tests and 1 sperm head abnormality test, in which the gamma-lactones were given by intraperitoneal injection at ≤ 2 g/kg bw/day, for ≤5 days.		Chromosome damage Germ cell mutation	-ve -ve	JECFA, 1998 (citing various reports)
In vitro					
Test system	Test conditions	Endpoint	Activation	Result	References
No studies on gamma-hexalactone were identified. Expert reviews briefly report the results of numerous studies on a number of related gamma-lactones. Though a few positive results have been observed, the overwhelming majority gave no evidence of activity (Adams et al. 1998; JECFA, 1998). JECFA noted that the positive results were only seen at “relatively high doses” and “may be artifactual” (JECFA, 1998).					

Hexan-4-olide (CAS RN 695-06-7) is a suspected mutagen. The CAESAR Mutagenicity model in the VEGA (Q)SAR platform predicts that the chemical is a mutagen (moderate reliability).

ECHA Annex III has been withdrawn as of April 2023: “The list of substances that are unlikely to benefit from the reduced information requirements, the so-called ‘Annex III inventory’, has been withdrawn.”

As taken from ECHA, 2016.

The reliability and applicability of this QSAR prediction as standalone source of toxicological information is limited and inappropriate for some complex endpoints like reprotoxicity or carcinogenicity. Nevertheless, for the toxicological assessment of this ingredient, this result was still taken into consideration and used within the WoE approach as a supportive tool, in combination with other sources of information when available, like experimental data or appropriate read-across.

“Background: The γ -hexalactone is a flavoring agent for alcoholic beverages, teas, breads, dairy products, coffees, buttery products among others. It presents low molecular weight and exhibits sweet fruity aroma with nuances of nuts. As far as we know, both literature and government regulations have gaps regarding the safe use of the γ -hexalactone. In this context, the main objective of this work was to evaluate the effects of γ -hexalactone through *in silico* and *in vitro* approaches. Methods: The *in silico* analysis was performed through four free online platforms (admetSAR, Osiris Property Explorer®, pkCSM platform and PreADMET) and consisted of comparative structural analysis with substances present in databases. The computational prediction was performed in the sense of complement and guide the *in vitro* tests. Regarding *in vitro* investigations, screening of cytotoxicity (assessed by cell proliferation and viability parameters) in lymphocytes exposed to γ -hexalactone for 72 h were carried out previously to determine non-cytotoxic concentrations. Following this screening, concentrations of 5.15, 0.515, and 0.0515 μ M were selected for the study of the respective potentials: genotoxic (assessed by DNA comet assay), chromosomal mutation (analysis of micronucleus frequency) and immunomodulatory (cytokine quantification using ELISA immunoassay). The results of *in vitro* assays were compared by one-way analysis of variance (ANOVA), followed by Bonferroni's post hoc test, conducted by statistic software. Results: The platform PreADMET pointed out that γ -hexalactone is potentially mutagenic and carcinogenic. The comet assay data corroborate with these results demonstrating that γ -hexalactone at 5.15 μ M caused lymphocytes DNA damage. In relation to cytokine secretion, the results indicate that lymphocytes were activated by γ -hexalactone at non-cytotoxic concentrations, involving an increase in the IL-1 levels in all tested concentrations, ranging from approximately 56 to 93%. The γ -hexalactone only at 5.15 μ M induced increase in the levels of IL-6 (~ 60%), TNF- α (~ 68%) and IFN- γ (~ 29%), but decreased IL-10 (~ 46%) in comparison with the negative control ($p < 0.05$). No change was observed in total lymphocytes or in cell viability at the concentrations tested. Conclusions: In summary, the γ -hexalactone demonstrated immunomodulatory and genotoxic effects at non-cytotoxic concentrations in healthy lymphocytes.” As taken from Zuravski L et al. 2019. BMC Pharmacol. Toxicol. 20(Suppl. 1), 79. PubMed, 2020 available at <https://pubmed.ncbi.nlm.nih.gov/31852517/>

γ -Hexalactone was assessed in the BlueScreen assay and found negative for both cytotoxicity (positive: <80% relative cell density) and genotoxicity, with and without metabolic activation (RIFM, 2013). BlueScreen is a human cell-based assay for measuring the genotoxicity and cytotoxicity of chemical compounds and mixtures. Additional assays on an equi-reactive read-across material were considered to fully assess the potential mutagenic or clastogenic effects of the target material.

There are no studies assessing the mutagenic and clastogenic activity of γ -hexalactone; however, read-across can be made to γ -valerolactone (CAS # 108-29-2; see Section VI).

The mutagenic activity of γ -valerolactone has been evaluated in a bacterial reverse mutation assay conducted in compliance with GLP regulations and in accordance with OECD TG 471 using the standard plate incorporation method. Salmonella typhimurium strains TA98, TA100, TA1535, TA1537, and Escherichia coli strain WP2uvrA were treated with γ -valerolactone in dimethyl sulfoxide (DMSO) at concentrations up to 5000 μ g/plate. No increases in the mean number of revertant colonies were observed at any tested concentration in the presence or absence of S9 (RIFM, 2017a). Under the conditions of the study, γ -valerolactone was not mutagenic in the Ames test, and this can be extended to γ -hexalactone.

The clastogenic activity of γ -valerolactone was evaluated in an *in vitro* micronucleus test conducted in compliance with GLP regulations and in accordance with OECD TG 487. Human peripheral blood lymphocytes were treated with γ -valerolactone in DMSO at concentrations up to 1001 μ g/mL

in the presence and absence of metabolic activation (S9) for 3 h and in the absence of metabolic activation for 24 h. γ -Valerolactone did not induce binucleated cells with micronuclei when tested up to the maximum allowed concentration in either non-activated or S9-activated test systems (RIFM, 2017b). Under the conditions of the study, γ -valerolactone was considered to be non-clastogenic in the in vitro micronucleus test, and this can be extended to gamma-hexalactone.

Based on the data available, γ -valerolactone does not present a concern for genotoxic potential, and this can be extended to gamma-hexalactone.

γ -Valerolactone (CAS # 108-29-2) was used as a read-across analog for the target material, γ -hexalactone (CAS # 695-06-7), for the genotoxicity endpoint.

- The target material and the read-across analog belong to the class of lactones.
- The key difference between the target material and the read-across analog is that target has an ethyl substituent at the fifth position, whereas the read-across analog has a methyl substituent at the fifth position on the carboxylic end. This structural difference is toxicologically insignificant.
- The similarity between the target material and the read-across analog is indicated by the Tanimoto score. Differences between the structures that affect the Tanimoto score are toxicologically insignificant.
- The physical–chemical properties of the target material and the read-across analog are sufficiently similar to enable a comparison of their toxicological properties.
- According to the OECD QSAR Toolbox v4.2, structural alerts for toxicological endpoints are consistent between the target material and the read-across analog.
- There is an “AN2|AN2 >> Michael-type addition on α,β -unsaturated carbonyl compounds|AN2 >> Michael-type addition on α,β -unsaturated carbonyl compounds >> Four- and Five-Membered Lactones|SN2|SN2 >> Alkylation, ring-opening SN2 reaction|SN2 >> Alkylation, ring-opening SN2 reaction >> 4- and 5-Membered Lactones” (DNA Binding [OASIS v1.4, QSAR Toolbox v4.2]) alert for both the target and the read-across analog. This is a typical structural alert for 4- or 5-membered lactones. It is believed that the mechanism of action for 5-membered lactones is associated with the presence of the α -methylidene group (α -methylene- γ -butyrolactones) in some Ames-active representatives of this class, which gives rise to the α,β -conjugated system. It has been suggested that the presence of the α -methylene- γ -lactone structural fragment is of critical importance for toxicity, but the exact mechanism has not been elucidated. The facility for Michael-type addition with the exocyclic α -methylene group on γ -lactone is also suggested to determine the biological activity. The absence of the α -methylidene group in both the target material and read-across analog suggests that both materials do not pose any genotoxic concern, and hence, the alerts are superseded.

- The target material and the read-across analog are expected to be metabolized similarly, as shown by the metabolism simulator.
- The structural alerts for the endpoints evaluated are consistent between the metabolites of the read-across analog and the target material.

As taken from Api AM et. al. Food and Chemical Toxicology (2022). Available at: <https://pubmed.ncbi.nlm.nih.gov/35817258/>

5.5. Cytotoxicity

High-throughput Assay Data

The US Environmental Protection Agency (EPA) evaluated gamma-caprolactone (CAS RN 695-06-7) in a series of high-throughput assays, which are publicly available on the US EPA's CompTox Dashboard (section BIOACTIVITY / sub-section TOXCAST:SUMMARY), available at the following URL: <https://comptox.epa.gov/dashboard>

US EPA provides the following data use considerations for ToxCast data: "The activity of a chemical in a specific assay does not necessarily mean that it will cause toxicity or an adverse health outcome. There are many factors that determine whether a chemical will cause a specific adverse health outcome. Careful review is required to determine the use of the data in a particular decision contexts. Interpretation of ToxCast data is expected to change over time as both the science and analytical methods improve."

A summary of the ToxCast assay data on gamma-caprolactone is provided below in Figure 1. Figure 1 proves an overview of the types of assays where activity was noted with this substance. The complete study details are available on US EPA's CompTox Dashboard.

Figure 1

5.6. Carcinogenicity

Carcinogenicity			
Species	Test conditions	Evidence of carcinogenicity	Reference
No studies were identified on gamma-lactone. A good-quality study on a structurally-related gamma-lactone is summarized briefly below.			
Rat and Mouse (50 per species per sex per dose)	STRUCTURALLY RELATED LACTONE A comprehensive NTP study on gamma-butyrolactone is reported in an expert review. Oral administration for 2 years (up to 525 or 450 mg/kg bw/day for mice and rats, respectively), followed by microscopic examination of a comprehensive range of tissues and organs.	None in rats or female mice. Equivocal in male mice. There was a marginal increase in adrenal tumours and hyperplasia in the low dose group. Not seen in high-dose group, but high mortality in this group (due to fighting) reduced sensitivity.	NTP, 1992

5.7. Irritation/immunotoxicity

Type of Test	Route of Exposure or Administration	Species/Test System	Dose Data	Reaction Severity	Reference
Standard Draize test	Administration onto the skin	Rodent - rabbit	500 mg/24H	Mild	FCTXAV Food and Cosmetics Toxicology. (London, UK) V.1-19, 1963-81. For publisher information, see FCTOD7. Volume(issue)/page/year: 17,791,1979

As taken from RTECS, 1997

A review noted that a maximization test using 12% in petrolatum produced no sensitization reactions in 30 male volunteers; another maximization test using the same concentration produced no sensitization reactions in 27 mixed-sex volunteers (cited in Opdyke, 1979).

gamma-Caprolactone applied full strength to intact or abraded rabbit skin for 24 hours under occlusion was mildly irritating (Moreno, 1977b).

Tested at 12% in petrolatum, gamma-caprolactone produced no irritation after a 48-hour closed patch test on human subjects (Epstein, 1997).

Hexan-4-olide (CAS RN 695-06-7) is a suspected skin sensitizer. The CAESAR skin sensitization model in the VEGA (Q)SAR platform predicts that the chemical is a sensitizer (moderate reliability).

ECHA Annex III has been withdrawn as of April 2023: "The list of substances that are unlikely to benefit from the reduced information requirements, the so-called 'Annex III inventory', has been withdrawn."

As taken from ECHA, 2016.

The reliability and applicability of this QSAR prediction as standalone source of toxicological information is limited and inappropriate for some complex endpoints like reprotoxicity or carcinogenicity. Nevertheless, for the toxicological assessment of this ingredient, this result was still

taken into consideration and used within the WoE approach as a supportive tool, in combination with other sources of information when available, like experimental data or appropriate read-across.

Limited skin sensitization studies are available for γ -hexalactone. Based on the existing data and read-across material 4-hydroxybutanoic acid lactone (CAS # 96-48-0; see Section VI), γ -hexalactone is not considered a skin sensitizer. The chemical structure of these materials indicate that they would not be expected to react with skin proteins directly (Roberts et al., 2007; Toxtree v3.1.0; OECD Toolbox v4.2). In a murine local lymph node assay (LLNA), read-across material 4-hydroxybutanoic acid lactone was not found to be sensitizing when tested up to 100% (ECHA, 2011). In a guinea pig maximization test, γ -hexalactone did not present reactions indicative of sensitization (RIFM, 1977). In 2 human maximization tests, no skin sensitization reactions were observed with γ -hexalactone at 12% (8280 $\mu\text{g}/\text{cm}^2$) in petrolatum (RIFM, 1977).

Based on the weight of evidence (WoE) from structural analysis, animal and human studies, and read-across material 4-hydroxybutanoic acid lactone, γ -hexalactone does not present a concern for skin sensitization under the current, declared levels of use. As taken from Api AM et. al. Food and Chemical Toxicology (2022). Available at: <https://pubmed.ncbi.nlm.nih.gov/35817258/>

5.8. All other relevant types of toxicity

High-throughput Assay Data

The US Environmental Protection Agency (EPA) evaluated gamma-caprolactone (CAS RN 695-06-7) in a series of high-throughput assays, which are publicly available on the US EPA's CompTox Dashboard (section BIOACTIVITY / sub-section TOXCAST:SUMMARY), available at the following URL: <https://comptox.epa.gov/dashboard>

US EPA provides the following data use considerations for ToxCast data: "The activity of a chemical in a specific assay does not necessarily mean that it will cause toxicity or an adverse health outcome. There are many factors that determine whether a chemical will cause a specific adverse health outcome. Careful review is required to determine the use of the data in a particular decision contexts. Interpretation of ToxCast data is expected to change over time as both the science and analytical methods improve."

A summary of the ToxCast assay data on gamma-caprolactone is provided below in Figure 1. Figure 1 proves an overview of the types of assays where activity was noted with this substance. The complete study details are available on US EPA's CompTox Dashboard.

Figure 1

6. Functional effects on

6.1. Broncho/pulmonary system

No data available to us at this time.

6.2. Cardiovascular system

No data available to us at this time.

6.3. Nervous system

"Neurotoxin: Acute solvent syndrome".

As taken from Haz-Map, 2020

6.4. Other organ systems, dependent on the properties of the substance

No data available to us at this time.

7. Addiction

JTI is not aware of any information that demonstrates that this ingredient has any addictive effect.

8. Burnt ingredient toxicity

This ingredient was considered as part of an overall safety assessment of ingredients added to tobacco in the manufacture of cigarettes. An expert panel of toxicologists reviewed the open

literature and internal toxicology data of 5 tobacco companies to evaluate a composite list of ingredients used in the manufacture of cigarettes. The conclusion of this report was that these ingredients did not increase the inherent biological activity of tobacco cigarettes, and are considered to be acceptable under conditions of intended use (Doull et al., 1994 & 1998).

Tobacco smoke condensates from cigarettes containing gamma-Hexalactone and an additive free, reference cigarettes were tested in a battery of in vitro and/or in vivo test(s). Within the sensitivity and specificity of the bioassay(s) the activity of the condensate was not changed by the addition of gamma-Hexalactone. Table below provides tested level(s) and specific endpoint(s).

Endpoint	Tested level (ppm)	Reference
Smoke chemistry	5	Carmines, 2002 & Rustemeier et al., 2002

9. Heated/vapor emissions toxicity

Aerosol from an electronic nicotine delivery system (ENDS) that creates a vapor by heating an e-liquid containing gamma-Hexalactone was tested in a battery of in vitro and/or in vivo test(s). Under the test conditions and within the sensitivity and specificity of the bioassay(s), no mutagenic, genotoxic or cytotoxic responses were observed when exposed to Aerosol Collected Matter (ACM) and/or aerosol Gas Vapor Phase (GVP) and no adverse findings from a 90-day in vivo repeat-dose inhalation toxicity study were observed after exposure to the aerosol even when exposure concentrations were the maximal amount that could be achieved with the specific product(s). These results are in contrast to those observed with combustible cigarette which showed mutagenic, genotoxic, cytotoxic and adverse effects upon exposure. The table below provides the highest tested level(s) and specific endpoint(s):

Endpoint	Tested level (ppm)	Reference
Aerosol chemistry	500	Logic (2019) Labstat International Inc. (2021)
In vitro genotoxicity	500	Logic (2019) Labstat International Inc. (2022)
In vitro cytotoxicity	500	Logic (2019) Labstat International Inc. (2022)
In vivo genotoxicity	0.82	Logic (2019)
Inhalation study	0.82	Logic (2019)

Aerosol from heated tobacco stick(s) containing gamma-Hexalactone was tested in aerosol chemistry and a battery of in vitro test(s). Under the test conditions and within the sensitivity and specificity of the bioassay(s), the activity of the total particulate matter (TPM) and/or gas vapor phase (GVP) were not increased by the addition of this ingredient when compared to TPM and/or GVP from reference combustible cigarettes. The table below provides the highest tested level(s) and specific endpoint(s):

Endpoint	Tested level (mg/stick)	Reference
Aerosol chemistry	0.271	Labstat International Inc. (2020a) Labstat International Inc. (2021a) Labstat International Inc. (2023a) JTI Heated Tobacco Stick Study Report(s)
In vitro genotoxicity	0.271	Labstat International Inc. (2020b) Labstat International Inc. (2021b) Labstat International Inc. (2023b) JTI Heated Tobacco Stick Study Report(s)
In vitro cytotoxicity	0.271	Labstat International Inc. (2020b) Labstat International Inc. (2021b) Labstat International Inc. (2023b) JTI Heated Tobacco Stick Study Report(s)

10. Ecotoxicity

10.1. Environmental fate

The Ecological Categorization Results from the Canadian Domestic Substances List state that 2(3H)-furanone, 5-ethylidihydro (CAS RN 695-06-7) is not persistent in the environment:

Media of concern leading to Categorization	Water
Experimental Biodegradation half-life (days)	Not Available
Predicted Ultimate degradation half-life (days)	15
MITI probability of biodegradation	09219
TOPKAT probability of biodegradation	1
EPI Predicted Ozone reaction half-life (days)	999
EPI Predicted Atmospheric Oxidation half-life (days)	1.961

Data accessed May 2017 on the OECD website.

EPISuite provides the following data:

Henrys Law Constant (25 deg C) [HENRYWIN v3.20]:

Bond Method :	1.81E-004 atm-m3/mole (1.83E+001 Pa-m3/mole)
Group Method:	6.00E-005 atm-m3/mole (6.08E+000 Pa-m3/mole)
Henrys LC [via VP/WSol estimate using User-Entered or Estimated values]:	HLC: 7.699E-007 atm-m3/mole (7.801E-002 Pa-m3/mole) VP: 0.165 mm Hg (source: MPBPVP) WS: 3.22E+004 mg/L (source: WSKOWWIN)

Log Octanol-Air Partition Coefficient (25 deg C) [KOAWIN v1.10]:

Log Kow used:	0.60 (KowWin est)
Log Kaw used:	-2.131 (HenryWin est)
Log Koa (KOAWIN v1.10 estimate):	2.731
Log Koa (experimental database):	None

Probability of Rapid Biodegradation (BIOWIN v4.10):

Biowin1 (Linear Model):	0.8674
Biowin2 (Non-Linear Model) :	0.9958
Biowin3 (Ultimate Survey Model):	3.0871 (weeks)
Biowin4 (Primary Survey Model) :	3.9120 (days)
Biowin5 (MITI Linear Model) :	0.8180
Biowin6 (MITI Non-Linear Model):	0.9219
Biowin7 (Anaerobic Linear Model):	0.7538
Ready Biodegradability Prediction:	YES

Hydrocarbon Biodegradation (BioHCwin v1.01):

Structure incompatible with current estimation method!

--------------------------	-----------

Atmospheric Oxidation (25 deg C) [AopWin v1.92]: Hydroxyl Radicals Reaction:

OVERALL OH Rate Constant =	5.4538 E-12 cm ³ /molecule-sec
Half-Life =	1.961 Days (12-hr day; 1.5E6 OH/cm ³)
Half-Life =	23.534 Hrs
Ozone Reaction:	No Ozone Reaction Estimation
Fraction sorbed to airborne particulates (phi): 8.54E-006 (Junge-Pankow, Mackay avg) 1.06E-008 (Koa method) Note: the sorbed fraction may be resistant to atmospheric oxidation	

Soil Adsorption Coefficient (KOCWIN v2.00):

Koc :	19.82 L/kg (MCI method)
Log Koc:	1.297 (MCI method)
Koc :	15.54 L/kg (Kow method)
Log Koc:	1.191 (Kow method)

Aqueous Base/Acid-Catalyzed Hydrolysis (25 deg C) [HYDROWIN v2.00]: Rate constants can NOT be estimated for this structure! **Volatilization from Water:** Henry LC: 6E-005 atm-m³/mole (estimated by Group SAR Method)

Half-Life from Model River:	11.52 hours
Half-Life from Model Lake:	215.2 hours (8.967 days)

Removal In Wastewater Treatment:

Total removal:	4.90 percent
Total biodegradation:	0.09 percent
Total sludge adsorption:	1.72 percent
Total to Air:	3.09 percent

(using 10000 hr Bio P,A,S)

Level III Fugacity Model:

	Mass Amount	Half-Life	Emissions
--	-------------	-----------	-----------

	(percent)	(hr)	(kg/hr)
Air	5.49	47.1	1000
Water	35	360	1000
Soil	59.4	720	1000
Sediment	0.0933	3.24e+003	0

Persistence Time: 339 hr

10.2. Aquatic toxicity

The Ecological Categorization Results from the Canadian Domestic Substances List state that 2(3H)-furanone, 5-ethylidihydro (CAS RN 695-06-7) is not inherently toxic to aquatic organisms:

Pivotal value for iT (mg/l)	824.8
Toxicity to fathead minnow (LC50 in mg/l) as predicted by Topkat v6.1	824.8
Toxicity to fish (LC50 in mg/l) as predicted by Ecosar v0.99g	96.93
Toxicity to fish (LC50 in mg/l) as predicted by Oasis Forecast M v1.10	8,006.7534
Toxicity to fish (LC50 in mg/l) as predicted by Aster	283.800969
Toxicity to fish (LC50 in mg/l) as predicted by PNN	2,693.04213
Toxicity to daphnia (EC50 in mg/l) as predicted by Topkat v6.1	61.7
Toxicity to fish, daphnia, algae or mysid shrimp (EC50 or LC50 in mg/l) as predicted by Ecosar v0.99g	1,703.956
Toxicity to fish (LC50 in mg/l) as predicted by Neutral Organics QSAR in Ecosar v0.99g	1.75E+001

Data accessed May 2017 on the OECD website.

ECOSAR Version 1.11 provides the following aquatic toxicity data for CAS RN 695-06-7:

Values used to Generate ECOSAR Profile
Log Kow : 0.603 (EPISuite Kowwin v1.68 Estimate)
Wat Sol : 6.507E+004 (mg/L, EPISuite WSKowwin v1.43 Estimate)

ECOSAR v1.11 Class-specific Estimations

Esters

ECOSAR Class	Organism	Duration	End Pt	Predicted mg/L (ppm)	
Esters :	Fish	96-hr	LC50	99.890	

Esters :	Daphnid	48-hr	LC50	241.153

SCIENTIFIC OPINION

Scientific Opinion on Flavouring Group Evaluation 10, Revision 3 (FGE.10Rev3):

Aliphatic primary and secondary saturated and unsaturated alcohols, aldehydes, acetals, carboxylic acids and esters containing an additional oxygenated functional group and lactones from chemical groups 9, 13 and 30¹

EFSA Panel on Food Contact Materials, Enzymes, Flavourings and Processing Aids (CEF)^{2,3}

European Food Safety Authority (EFSA), Parma, Italy

ABSTRACT

The Panel on Food Contact Materials, Enzymes, Flavourings and Processing Aids of the European Food Safety Authority was requested to evaluate 63 flavouring substances in the Flavouring Group Evaluation 10, including additional two substances in this Revision 3, using the Procedure in Commission Regulation (EC) No 1565/2000. For one substance [FL-no: 10.170] a concern for genotoxicity could not be ruled out. The remaining 62 substances were evaluated through a stepwise approach (the Procedure) that integrates information on structure-activity relationships, intake from current uses, toxicological threshold of concern, and available data on metabolism and toxicity. The Panel concluded that the 62 substances do not give rise to safety concerns at their levels of dietary intake, estimated on the basis of the MSDI approach. Besides the safety assessment of these flavouring substances, the specifications for the materials of commerce have also been considered. For four substances evaluated through the Procedure, the stereoisomeric composition has not been specified sufficiently.

SUMMARY

The European Food Safety Authority (EFSA) asked the Panel on Food Contact Materials, Enzymes, Flavourings and Processing Aids (the Panel) to advise the Commission on the implications for human health of chemically defined flavouring substances used in or on foodstuffs in the Member States. In particular, the Panel was requested to evaluate 63 flavouring substances in the Flavouring Group Evaluation 10, Revision 3 (FGE.10Rev3), using the Procedure as referred to in the Commission Regulation (EC) No 1565/2000. These flavouring substances belong to chemical groups 9, 13 and 30, Annex I of the Commission Regulation (EC) No 1565/2000.

The present revision of FGE.10, FGE.10Rev3, includes the assessment of two additional candidate substances [FL-no: 09.951 and 10.170].

The flavouring substances are alcohols, aldehydes, acetals, carboxylic acids and esters containing additional oxygenated functional groups and lactones.

Thirty-six of the candidate substances possess one or more chiral centres and eight can exist as geometrical isomers due to the presence and the position of a double bond. For five of these substances [FL-no: 10.038, 10.040, 10.059, 10.063 and 10.170] the stereoisomeric composition / composition of mixture has not been specified sufficiently.

Fifty-five candidate substances belong to structural class I, six belong to structural class II, and two belong to structural class III according to the decision tree approach presented by Cramer et al. (1978).

Fifty of the flavouring substances in the present group have been reported to occur naturally in a wide range of food items.

In its evaluation, the Panel as a default used the “Maximised Survey-derived Daily Intakes” (MSDI) approach to estimate the *per capita* intakes of the flavouring substances in Europe. However, when the Panel examined the information provided by the European Flavouring Industry on the use levels in various foods, it appeared obvious that the MSDI approach in a number of cases would grossly underestimate the intake by regular consumers of products flavoured at the use level reported by the Industry, especially in those cases where the annual production values were reported to be small. In consequence, the Panel had reservations about the data on use and use levels provided and the intake estimates obtained by the MSDI approach.

In the absence of more precise information that would enable the Panel to make a more realistic estimate of the intakes of the flavouring substances, the Panel has decided also to perform an estimate of the daily intakes per person using a “modified Theoretical Added Maximum Daily Intake” (mTAMDI) approach based on the normal use levels reported by Industry. In those cases where the mTAMDI approach indicated that the intake of a flavouring substance might exceed its corresponding threshold of concern, the Panel decided not to carry out a formal safety assessment using the Procedure. In these cases the Panel requires more precise data on use and use levels.

The candidate substances which have been assigned to structural class I have estimated European daily *per capita* intakes (MSDI) ranging from 0.0012 to 1500 microgram. The candidate substances from structural class II have MSDIs ranging from 0.0012 to 1.2 microgram and the two candidate substances assigned to structural class III have estimated European daily *per capita* intakes of 0.011 and 1.2 microgram (Table 6.1). These intakes are below the thresholds of concern of 1800, 540 and 90 microgram/person/day for structural class I, II and III, respectively.

The combined estimated daily *per capita* intake as flavourings of the 55 candidate substances assigned to structural class I is 1600 microgram, which does not exceed the threshold of concern for a substance belonging to structural class I of 1800 microgram/person/day. Likewise, the combined estimated daily *per capita* intake as flavouring of the six candidate substances assigned to structural class II is 1.2

microgram, which does not exceed the threshold of concern for a substance belonging to structural class II of 540 microgram/person/day.

For 5-pentyl-3H-furan-2-one [FL-no: 10.170], the flavour Industry informs that the commercial product is a mixture of two structural isomers – 2/3 is the named compound (5-pentyl-3H-furan-2-one) and 1/3 is the structural isomer - 5-pentyl-5H-furan-2-one. This latter isomer is identical to [FL-no: 10.054], which is an alpha, beta-unsaturated alcohol (after hydrolysis of the lactone), allocated to subgroup 4.1 of FGE.19 (FGE.217). The Panel concluded that 5-pentyl-3H-furan-2-one [FL-no: 10.170] should not be evaluated through the Procedure until the additional genotoxicity data for [FL-no: 10.054] are available, as stated in FGE 217.

The Panel reconsidered the fact that 1-hydroxypropan-2-one [FL-no: 07.169] is an endogenous metabolite of acetone. Acetone is endogenously formed from the degradation of body fat/fatty acids and occurs in the blood of healthy humans not exposed to external sources of acetone in amounts of approximately 4 - 12 mg/person, corresponding to 0.7 to 2 mg/l blood. Under these conditions, the majority of the acetone in blood would be metabolised to 1-hydroxypropan-2-one, which is rapidly further metabolised to endogenous compounds (methylglyoxal, pyruvate and glucose) in the methylglyoxal pathway. The estimated exposure of 0.22 microgram/capita/day is considerably lower than that resulting from the metabolism of acetone and would not significantly add to the internal exposure to 1-hydroxypropan-2-one in the body and would not perturb the normal catabolism of the compound to innocuous endogenous products. The Panel therefore decided that further genotoxicity data are not required and that the substance could be taken through the Procedure.

For the remaining candidate substances, the genotoxic potential cannot be assessed adequately, however, from the limited data available there were no indications that genotoxicity for these substances should give rise to safety concern. So, 62 substances are evaluated through the Procedure in the present revision of FGE.10.

It can be anticipated that, at the estimated levels of intake as flavouring substances, 59 of the alcohols, aldehydes, acetals, carboxylic acids and esters with an additional oxygenated functional group and aliphatic lactones included in the present FGE are generally hydrolysed and completely metabolised to innocuous products, many of which are endogenous in humans. For three of the flavouring substances [FL-no: 02.242, 06.097 and 09.824], it cannot be concluded that they are metabolised to innocuous products. Adequate margins of safety could be established for these three substances in step B4 of the Procedure.

It was noted that where toxicity data were available they were consistent with the conclusions in the present Flavouring Group Evaluation using the Procedure.

It was considered that on the basis of the default MSDI approach that the flavouring substances, to which the Procedure have been applied, would not give rise to safety concerns at the estimated levels of intake arising from their use as flavouring substances.

The mTAMDI for the flavouring substances, for which use levels information is available, range from 800 to 5100 microgram/person/day. For 58 of these substances the mTAMDI is above the threshold of concern of their structural classes and for three substances the mTAMDI is below the threshold. The three flavouring substances which have mTAMDI intake estimates below the threshold of concern for their structural class are also expected to be metabolised to innocuous products. For two flavouring substances use levels have not been provided and no mTAMDI could be estimated. Thus, for 60 flavouring substances, further information is required. This would include more reliable intake data and then, if required, additional toxicological data.

Thus, in conclusion, 62 of the 63 flavouring substances were evaluated through the Procedure (based on the MSDI approach), as one flavouring substance, 5-pentyl-3H-furan-2-one [FL-no: 10.170] could not be evaluated through the Procedure until adequate genotoxicity data become available.

In order to determine whether the conclusion for the candidate substances evaluated using the Procedure can be applied to the materials of commerce, it is necessary to consider the available specifications. Specifications including complete purity criteria and identity for the materials of commerce have been provided for 58 flavouring substances. For four substances [FL-no: 10.038, 10.040, 10.059 and 10.063] information on composition of mixture and / or stereoisomerism has not been specified sufficiently. For one substance [FL-no: 10.063] an identity test is missing.

Thus, the final evaluation of the materials of commerce cannot be performed for four substances [FL-no: 10.038, 10.040, 10.059 and 10.063], pending further information.

For the remaining 58 candidate substances [FL-no: 02.132, 02.198, 02.242, 05.149, 06.088, 06.090, 06.095, 06.097, 06.102, 06.135, 07.169, 08.053, 08.082, 08.090, 08.103, 08.113, 09.333, 09.345 - 09.354, 09.360, 09.502, 09.558, 09.565, 09.580, 09.590, 09.601, 09.626, 09.629, 09.633, 09.634, 09.644, 09.683, 09.815, 09.824, 09.832, 09.833, 09.862, 09.874, 09.916, 09.951, 10.039, 10.045, 10.047 - 10.049, 10.052, 10.055, 10.058, 10.068 and 10.168] the Panel concluded that they would present no safety concern at the estimated levels of intake based on the MSDI approach.

BACKGROUND

Regulation (EC) No 2232/96 of the European Parliament and the Council (EC, 1996a) lays down a Procedure for the establishment of a list of flavouring substances the use of which will be authorised to the exclusion of all other substances in the EU. In application of that Regulation, a Register of flavouring substances used in or on foodstuffs in the Member States was adopted by Commission Decision 1999/217/EC (EC, 1999a), as last amended by Commission Decision 2009/163/EC (EC, 2009a). Each flavouring substance is attributed a FLAVIS-number (FL-number) and all substances are divided into 34 chemical groups. Substances within a group should have some metabolic and biological behaviour in common.

Substances which are listed in the Register are to be evaluated according to the evaluation programme laid down in Commission Regulation (EC) No 1565/2000 (EC, 2000a), which is broadly based on the Opinion of the Scientific Committee on Food (SCF, 1999a). For the submission of data by the manufacturer, deadlines have been established by Commission Regulation (EC) No 622/2002 (EC, 2002b).

The FGE is revised to include substances for which data were submitted after the deadline as laid down in Commission Regulation (EC) No 622/2002 and to take into account additional information that has been made available since the previous Opinion on this FGE.

The Revision also includes newly notified substances belonging to the same chemical groups evaluated in this FGE.

After the completion of the evaluation programme the Union List of flavouring substances for use in or on foods in the EU shall be adopted (Article 5 (1) of Regulation (EC) No 2232/96) (EC, 1996a).

HISTORY OF THE EVALUATION

The first version of the Flavouring Group Evaluation 10 (FGE.10) dealt with 51 alcohols, aldehydes, acetals, carboxylic acids and esters containing an additional oxygenated functional group and lactones.

The first revision of FGE.10, FGE.10Rev1, included the assessment of eight additional candidate substances [FL-no: 06.088, 06.095, 06.102, 06.135, 09.565, 09.916, 10.040 and 10.168] and additional information on 32 substances [FL-no: 02.132, 02.198, 02.242, 06.090, 06.097, 07.169, 08.090, 09.333, 09.349, 09.360, 09.502, 09.580, 09.590, 09.601, 09.629, 09.633, 09.644, 09.683, 09.815, 09.824, 09.832, 09.862, 09.874, 10.038, 10.039, 10.043, 10.045, 10.048, 10.049, 10.052, 10.058 and 10.068] which had become available since the first FGE. Furthermore, substance [FL-no: 10.043], which can be metabolised to an alpha, beta-unsaturated ketone, was withdrawn from FGE.10Rev1 to be evaluated together with other alpha, beta-unsaturated ketones in FGE.217 (EFSA, 2008b).

The second revision of FGE.10 concerned the assessment of three additional candidate substances [FL-no: 08.113, 10.059 and 10.063] as well as additional information submitted by the Industry on the stereoisomeric composition/composition of mixture requested in FGE.10Rev1 for eight substances [FL-no: 06.088, 06.095, 06.135, 09.565, 09.916, 10.038, 10.040 and 10.168], and identity information for [FL-no: 06.088 and 06.095].

	2011	
FGE.10Rev3	1 February 2012	63

The present revision of FGE.10, FGE.10Rev3, includes the assessment of two additional candidate substances [FL-no: 09.951 and 10.170]. No toxicity or metabolism data were provided for these two substances. A search in open literature was conducted for metabolism, genotoxicity, repeated dose toxicity as well as reproductive/developmental toxicity for [FL-no: 09.951 and 10.170]. This search did not reveal any pertinent new information on the two substances.

FGE.10Rev3 also include additional information submitted by the Industry on specifications for [FL-no: 06.135 and 08.113] which had been requested in FGE.10Rev2.

TERMS OF REFERENCE

The European Food Safety Authority (EFSA) is requested to carry out a risk assessment on flavouring substances in the register (Commission decision 1999/217/EC), according to Commission Regulation (EC) No 1565/2000 (EC, 2000a), prior to their authorisation and inclusion in the Union list (Regulation (EC) No 1334/2008). In addition, the Commission requested EFSA to evaluate newly notified flavouring substances, where possible, before finalising the evaluation programme. The evaluation programme was finalised at the end of 2009.

After the finalisation of the evaluation programme, in their letters of the 30th July 2010 and 20th September 2010, the Commission requested EFSA to carry out an evaluation of the flavouring substances 5-pentyl-3H-furan-2-one [FL-no: 10.170] and dioctyl adipate [FL-no: 09.951], also according to Commission Regulation (EC) No 1565/2000 (EC, 2000a).

ASSESSMENT

1. Presentation of the Substances in Flavouring Group Evaluation 10, Revision 3

1.1. Description

The present Flavouring Group Evaluation 10, Revision 3 (FGE.10Rev3), using the Procedure as referred to in the Commission Regulation (EC) No 1565/2000 (EC, 2000a) (The Procedure – shown in schematic form in Annex I of this FGE), deals with 63 alcohols, aldehydes, acetals, carboxylic acids and esters containing an additional oxygenated functional group and lactones from chemical groups 9, 13 and 30, Annex I of Commission Regulation (EC) No 1565/2000 (EC, 2000a).

The flavouring substances (candidate substances) under consideration are listed in Table 1, as well as their chemical Register name, FLAVIS- (FL-), Chemical Abstract Service- (CAS-), Council of Europe- (CoE-) and Flavor and Extract Manufacturers Association- (FEMA-) numbers, structure and specifications.

The outcome of the Safety Evaluation is summarised in Table 2a.

Fifteen candidate substances are aliphatic lactones [FL-no: 10.038, 10.039, 10.040, 10.045, 10.047, 10.048, 10.049, 10.052, 10.055, 10.058, 10.059, 10.063, 10.068, 10.168 and 10.170]; thirty-two candidate substances are esters or diesters [FL-no: 09.333, 09.345 - 09.354, 09.360, 09.502, 09.558, 09.565, 09.580, 09.590, 09.601, 09.626, 09.629, 09.633, 09.634, 09.644, 09.683, 09.815, 09.824, 09.832, 09.833, 09.862, 09.874, 09.916 and 09.951]; six candidate substances are acetals [FL-no: 06.088, 06.090, 06.095, 06.097, 06.102 and 06.135]; one candidate substance is an alpha-hydroxyacid

[FL-no: 08.090]; one candidate substance is a ketoalcohol [FL-no: 07.169]; one candidate substance is an alkoxy-alcohol [FL-no: 02.242]; two candidate substances are diols [FL-no: 02.132 and 02.198]; one candidate substance is a dialdehyde [FL-no: 05.149] and four candidate substances are aliphatic dicarboxylic acids [FL-no: 08.053, 08.082, 08.103 and 08.113].

The hydrolysis products of candidate esters, lactones and acetals as well as their evaluation status are listed in Table 2b.

The candidate substances are structurally related to 29 aliphatic lactones (supporting substances) evaluated at the 49th JECFA meeting (JECFA, 1998a) and to 47 aliphatic primary alcohols, aldehydes, carboxylic acids, acetals and esters containing additional oxygenated functional groups evaluated at the 53rd JECFA meeting (JECFA, 2000c). These supporting substances are listed in Table 3, together with their evaluation status.

1.2. Stereoisomers

It is recognised that geometrical and optical isomers of substances may have different properties. Their flavour may be different, they may have different chemical properties resulting in possible variation of their absorption, distribution, metabolism, elimination and toxicity. Thus, information must be provided on the configuration of the flavouring substance, i.e. whether it is one of the geometrical/optical isomers, or a defined mixture of stereoisomers. The available specifications of purity will be considered in order to determine whether the safety evaluation carried out for candidate substances for which stereoisomers may exist can be applied to the material of commerce. Flavouring substances with different configurations should have individual chemical names and codes (CAS number, FLAVIS number, etc.).

Thirty-six of the substances possess one or more chiral centres [FL-no: 02.132, 02.198, 06.088, 06.090, 06.095, 06.135, 08.090, 09.333, 09.346, 09.349, 09.360, 09.502, 09.580, 09.590, 09.601, 09.629, 09.633, 09.644, 09.683, 09.815, 09.824, 09.832, 09.862, 09.874, 09.916, 10.038, 10.039, 10.040, 10.045, 10.048, 10.049, 10.052, 10.058, 10.068, 10.168 and 10.170]. For thirty-five substances the stereoisomeric composition has been specified. For [FL-no: 10.170] the Industry has informed that the commercial substance is a mixture of two structural isomers. One of these isomers possesses a chiral centre for which the configuration has not been specified.

Due to the presence and the position of a double bond, eight substances can exist as geometrical isomers [FL-no: 09.350, 09.351, 09.565, 10.038, 10.039, 10.040, 10.059 and 10.063]. For four of the substances [FL-no: 10.038, 10.040, 10.059 and 10.063] the stereoisomeric composition / composition of stereoisomeric mixture has not been specified sufficiently. Industry has stated that [FL-no: 10.038 and 10.040] exist as mixtures of (Z)- and (E)-isomers (EFFA, 2010a), however, the composition of the isomeric mixtures have to be provided.

1.3. Natural Occurrence in Food

Fifty of the flavouring substances have been reported to occur in one or more of the following food items: fruits (apple, pineapple, melon, guava, banana, starfruit, papaya, raspberry, mango, plum, citrus), oats, chestnut, juice, butter, meat, cheese, milk and milk products, skimmed milk powder, green tea, coffee, beer, wine and whisky.

Quantitative data on the natural occurrence in food have been reported for thirty-eight of the candidate substances (TNO, 2000; TNO, 2010). These reports include:

1.3.1 Candidate substances reported to occur in food (TNO, 2000; TNO, 2010)

FL-no:	Name:	Quantitative data reported:
02.198	Octane-1,3-diol	Up to 21 mg/kg in apple and up to 95.1 mg/kg in apple juice
02.242	2-Butoxyethan-1-ol	0.02 mg/kg in mozzarella cheese
06.088	2-Ethyl-4-methyl-1,3-	Up to 2 mg/kg in port wine
06.095	4-Methyl-2-propyl-1,3-	Up to 2 mg/kg in port wine
06.097	1,1,3-Triethoxypropane	Up to 3 mg/kg in pear brandy and less than 0.8 mg/kg in whisky
06.135	2-Isobutyl-4-methyl-1,3-dioxolane	Up to 2 mg/kg in port wine
07.169	1-Hydroxypropan-2-one	Up to 4 mg/kg in coffee
08.103	Nonanedioic acid	Up to 1.5 mg/kg in beer
09.590	Isobutyl lactate	20 mg/kg in port wine
09.916	Ethyl 3-hydroxyoctanoate	Up to 0.05 mg/kg in papaya, 0.02 mg/kg in orange juice and 0.03
10.045	Heptano-1,5-lactone	Up to 0.4 mg/kg in green tea
10.047	Hexadecano-1,16-lactone	0,0145 mg/kg in skimmed milk powder
10.048	Hexadecano-1,4-lactone	Up to 16.7 mg/kg in heated butter
10.049	Hexadecano-1,5-lactone	Up to 10.6 mg/kg in butter and up to 1.3 mg/kg in heated lamb and mutton fat

According to TNO, 13 of the substances have not been reported in any food items. These substances are listed in Table 1.3.1 (TNO, 2000; TNO, 2010):

1.3.1 Candidate substances not reported to occur in food (TNO, 2000; TNO, 2010)

FL-no:	Name:
06.102	2-Hexyl-5-hydroxy-1,3-dioxane
08.113	Succinic acid, disodium salt
09.502	Ethyl butyryl lactate
09.633	Methyl 5-hydroxydecanoate
09.644	Methyl lactate
09.824	Ethyl 2-acetylbutyrate
09.832	Ethyl 3-acetohexanoate
09.833	iso-Propyl 4-oxopentanoate
09.874	Di(2-methylbutyl) malate
10.040	Dec-8-eno-1,5-lactone
10.059	Hexadec-7-en-1,16-lactone
10.063	Hexadec-9-en-1,16 lactone
10.068	Pentadecano-1,14-lactone

2. Specifications

Purity criteria for the substances have been provided by the Flavouring Industry (EFFA, 2003c; EFFA, 2004ag; Flavour Industry, 2011a; Flavour Industry, 2010g; Flavour Industry, 2010n; Flavour Industry, 2011g) (Table 1).

Judged against the requirements in Annex II of Commission Regulation (EC) No 1565/2000 (EC, 2000a), this information is adequate for 62 substances. For one substance [FL-no: 10.063] an identity test is missing.

Furthermore, for five substances [FL-no: 10.038, 10.040, 10.059, 10.063 and 10.170], the stereoisomeric composition has not been specified sufficiently (see Section 1.2 and Table 1).

3. Intake Data

Annual production volumes of the flavouring substances as surveyed by the Industry can be used to calculate the “Maximised Survey-derived Daily Intake” (MSDI) by assuming that the production figure only represents 60 % of the use in food due to underreporting and that 10 % of the total EU population are consumers (SCF, 1999a).

However, the Panel noted that due to year-to-year variability in production volumes, to uncertainties in the underreporting correction factor and to uncertainties in the percentage of consumers, the reliability of intake estimates on the basis of the MSDI approach is difficult to assess.

The Panel also noted that in contrast to the generally low *per capita* intake figures estimated on the basis of this MSDI approach, in some cases the regular consumption of products flavoured at use levels reported by the Flavour Industry in the submissions would result in much higher intakes. In such cases, the human exposure thresholds below which exposures are not considered to present a safety concern might be exceeded.

Considering that the MSDI model may underestimate the intake of flavouring substances by certain groups of consumers, the SCF recommended also taking into account the results of other intake assessments (SCF, 1999a).

One of the alternatives is the “Theoretical Added Maximum Daily Intake” (TAMDI) approach, which is calculated on the basis of standard portions and upper use levels (SCF, 1995) for flavourable beverages and foods in general, with exceptional levels for particular foods. This method is regarded as a conservative estimate of the actual intake by most consumers because it is based on the assumption that the consumer regularly eats and drinks several food products containing the same flavouring substance at the upper use level.

One option to modify the TAMDI approach is to base the calculation on normal rather than upper use levels of the flavouring substances. This modified approach is less conservative (e.g., it may underestimate the intake of consumers being loyal to products flavoured at the maximum use levels reported) (EC, 2000a). However, it is considered as a suitable tool to screen and prioritise the flavouring substances according to the need for refined intake data (EFSA, 2004a).

3.1. Estimated Daily *per Capita* Intake (MSDI Approach)

The intake estimation is based on the Maximised Survey-derived Daily Intake (MSDI) (SCF, 1999) approach, which involves the acquisition of data on the amounts used in food as flavourings (SCF, 1999a). These data are derived from surveys on annual production volumes in Europe. These surveys were conducted in 1995 by the International Organization of the Flavour Industry, in which flavour manufacturers reported the total amount of each flavouring substance incorporated into food sold in the EU during the previous year (IOFI, 1995). The intake approach does not consider the possible natural occurrence in food.

Average *per capita* intake (MSDI) is estimated on the assumption that the amount added to food is consumed by 10 % of the population⁴ (Eurostat, 1998). This is derived for candidate substances from estimates of annual volume of production provided by Industry and incorporates a correction factor of 0.6 to allow for incomplete reporting (60 %) in the Industry surveys (SCF, 1999a).

The total annual volumes of production of the candidate substances from use as flavouring substances in Europe has been reported to be approximately 13220kg (EFFA, 2000c; EFFA, 2003d; EFFA,

⁴ EU figure 375 millions. This figure relates to EU population at the time for which production data are available, and is consistent (comparable) with evaluations conducted prior to the enlargement of the EU. No production data are available for the enlarged EU.

2008b; Flavour Industry, 2010g; Flavour Industry, 2010n). For the 60 of the 76 supporting substances the annual volume of production is 357000 kg (JECFA, 1999b; JECFA, 2000b).

On the basis of the annual volumes of production reported for the candidate substances, the daily *per capita* intakes for each of these flavourings have been estimated (Table 2a).

98 % of the total annual volume of production for the candidate substances is accounted for by three substances, succinic acid disodium salt [FL-no: 08.113], hexadec-9-en-1,16-lactone [FL-no: 10.063] and diethyl maleate [FL-no: 09.351]. The estimated daily *per capita* intake of succinic acid disodium salt from use as a flavouring substance is 1500 microgram, that of hexadec-9-en-1,16-lactone is 48 microgram and that of diethyl maleate is 12 microgram. The daily *per capita* intakes for each of the remaining substances are less than 10 microgram (Table 2a).

3.2. Intake Estimated on the Basis of the Modified TAMDI (mTAMDI)

The method for calculation of modified Theoretical Added Maximum Daily Intake (mTAMDI) values is based on the approach used by SCF up to 1995 (SCF, 1995).

The assumption is that a person may consume a certain amount of flavourable foods and beverages per day.

For 61 candidate substances information on food categories and normal and maximum use levels^{5,6,7} were submitted by the Flavour Industry (EFFA, 2001a; EFFA, 2003c; EFFA, 2003s; EFFA, 2004ag; EFFA, 2007a; Flavour Industry, 2006a; Flavour Industry, 2010g; Flavour Industry, 2010n). For two substances [FL-no: 06.135 and 08.113] no use levels have been provided for the food categories as listed in Commission Regulation (EC) No 1565/2000.

The candidate substances, for which use levels have been provided, are used in flavoured food products divided into the food categories, outlined in Annex III of the Commission Regulation (EC) No 1565/2000 (EC, 2000a), as shown in Table 3.1. For the present calculation of mTAMDI, the reported normal use levels were used. In the case where different use levels were reported for different food categories the highest reported normal use level was used.

According to the Flavour Industry the normal use levels for the candidate substances, for which use levels have been provided, are in the range of 1 - 101 mg/kg food, and the maximum use levels are in the range of 5 - 1005 mg/kg (EFFA, 2001a; EFFA, 2003c; EFFA, 2003s; EFFA, 2004ag; EFFA, 2007a; Flavour Industry, 2006a; Flavour Industry, 2010g; Flavour Industry, 2010n).

⁵ "Normal use" is defined as the average of reported usages and "maximum use" is defined as the 95th percentile of reported usages (EFFA, 2002i).

⁶ The normal and maximum use levels in different food categories (EC, 2000) have been extrapolated from figures derived from 12 model flavouring substances (EFFA, 2004e).

⁷ The use levels from food category 5 "Confectionery" have been inserted as default values for food category 14.2 "Alcoholic beverages" for substances for which no data have been given for food category 14.2 (EFFA, 2007a).

Table 3.1 Use of Candidate Substances in Various Food Categories for 61 Candidate Substances for which Data on Use have been provided.

Food category	Description	Flavourings used*
01.0	Dairy products, excluding products of category 2	All except [FL-no: 09.951]
02.0	Fats and oils, and fat emulsions (type water-in-oil)	All except [FL-no: 09.951]
03.0	Edible ices, including sherbet and sorbet	All except [FL-no: 09.951]
04.1	Processed fruits	All except [FL-no: 09.951]
04.2	Processed vegetables (incl. mushrooms & fungi, roots & tubers, pulses and legumes), and nuts & seeds	Only [FL-no: 10.170]
05.0	Confectionery	All except [FL-no: 09.951]
06.0	Cereals and cereal products, incl. flours & starches from roots & tubers, pulses & legumes, excluding bakery	All except [FL-no: 09.951]
07.0	Bakery wares	All except [FL-no: 09.951]
08.0	Meat and meat products, including poultry and game	All except [FL-no: 10.170]
09.0	Fish and fish products, including molluscs, crustaceans and echinoderms	All except [FL-no: 08.090, 09.551 and 10.170]
10.0	Eggs and egg products	None
11.0	Sweeteners, including honey	None
12.0	Salts, spices, soups, sauces, salads, protein products etc.	All except [FL-no: 06.095, 09.551 and 09.644]
13.0	Foodstuffs intended for particular nutritional uses	All except [FL-no: 06.095, 09.551, 09.644 and 10.170]
14.1	Non-alcoholic ("soft") beverages, excl. dairy products	All except [FL-no: 09.951]
14.2	Alcoholic beverages, incl. alcohol-free and low-alcoholic counterparts	All except [FL-no: 09.951]
15.0	Ready-to-eat savouries	All except [FL-no: 09.951]
16.0	Composite foods (e.g. casseroles, meat pies, mincemeat) - foods that could not be placed in categories 1 – 15	All

* Information on use levels has not been provided for [FL-no: 06.135 and 08.113]

The mTAMDI values for the 54 candidate substances from structural class I, for which use levels have been reported, range from 800 to 5100 microgram/person/day, for the five candidate substances from structural class II, for which use levels are available, the mTAMDI range from 3800 to 3900 microgram/person/day for each. For the two candidate substances from structural class III the mTAMDI are 3800 and 4100 microgram/person/day.

For detailed information on use levels and intake estimations based on the mTAMDI approach, see Section 6 and Annex II.

4. Absorption, Distribution, Metabolism and Elimination

In general, lactones are formed by acid-catalysed intramolecular cyclisation of hydroxycarboxylic acids. In an aqueous environment, a pH-dependent equilibrium is established between the open-chain

hydroxycarboxylate anion and the lactone ring. In basic and neutral media, such as blood, the open-chain hydroxycarboxylate anion is favoured while in acidic media, such as gastric juice and urine, the lactone ring is favoured. Enzymes, such as lactonase, may catalyse the hydrolysis reaction, but for simple saturated lactones, the ring-opening reaction and reverse cyclization are in equilibrium, mainly controlled by pH conditions. Both the aliphatic lactones and the ring-opened hydroxycarboxylic acids can be absorbed from the gastrointestinal tract. However, the simple lactones, with low molecular weight, being uncharged may cross the cell membrane more easily than the acidic form, which penetrates the cells as a weak electrolyte. The hydroxycarboxylic acid obtained from lactone hydrolysis enters the fatty acid pathway and undergoes alpha- or beta-oxidation and cleavage to form acetyl CoA and a chain-shortened carboxylic acid. The carboxylic acid is then reduced by 2-carbon fragments until either acetyl CoA or propionyl CoA is produced. These fragments are then metabolised in the citric acid cycle. The Panel anticipated that the two unsaturated omega-lactones ([FL-no: 10.059], hexadec-7-en-1,16-lactone and [FL-no: 10.063], hexadec-9-en-1,16-lactone) are metabolised like the structurally related saturated lactones, namely through ring opening followed by fatty acid degradation.

In humans, paraoxonase (PON1), a serum enzyme belonging to the class of A-carboxyesterases (Aldridge, 1953), is known to rapidly hydrolyse a broad range of aliphatic lactone substrates including beta-, gamma-, delta- and omega-lactones and lactones fused to alicyclic rings such as 2-(2-hydroxycyclopent-4-enyl)ethanoic acid gamma-lactone (Billecke et al., 2000). Activities of paraoxonase isoenzymes (Q & R) in human blood exhibit a bimodal distribution that is accounted for by a Q/R (glutamine or arginine) polymorphism with Q-type homozygotes showing a lower activity than QR heterozygotes or R homozygotes (Humbert et al., 1993).

Mono- and di-esters included in the present FGE are expected to undergo hydrolysis in humans to yield their corresponding alcohol (linear or branched-chain aliphatic alcohols) and acid components (i.e. alpha-, beta- or gamma-keto or hydroxy acids, or simple aliphatic acids, diacids or triacids), which would be further metabolised and excreted. It has to be noted that the 2-acetyl butyric acid, formed as one of the hydrolysis products of the candidate substance ethyl 2-acetylbutyrate [FL-no: 09.824], has some structural similarities to valproic acid, which, together with a number of its derivatives, has been recognised as teratogenic in rodents and in humans (Nau and Löscher, 1986; Samren et al., 1997; Kaneko et al., 1999). Although it can be predicted that 2-acetylbutyric acid is further metabolised through the usual pathways of detoxication for carboxylic acids (i.e. mainly *via* glucuronidation reaction), the structural similarity with valproic acid does not allow the prediction that ethyl 2-acetylbutyrate [FL-no: 09.824] is metabolised only to innocuous products.

The presence of a second oxygenated functional group has little if any effect on hydrolysis of these esters. The most probable metabolic reactions of the hydrolysis products are, oxidation of alcohols to aldehydes and acids, conjugation of alcohols and acids to glucuronides and sulphates and beta- and omega-oxidation of carboxylic acids.

Beta-keto acids and derivatives like acetoacetic acid undergo ready decarboxylation. Along with alpha-keto and alpha-hydroxyacids, they yield breakdown products, which are incorporated into normal biochemical pathways. The gamma-keto acids and related substances may undergo complete or partial beta-oxidation to yield metabolites that are eliminated in the urine. Omega-substituted derivatives are readily oxidised and/or excreted in the urine. Simple aliphatic di- and tricarboxylic acids participate in the tricarboxylic acid cycle. For instance, succinic acid is a normal intermediary metabolite and a constituent of the citric acid cycle; it occurs normally in human urine (1.9 - 8.8 mg/L). Succinic acid is readily metabolized when administered to animals, but may be partly excreted unchanged in the urine if large doses are given (Patty, 1993, Vol. II, p. 3579).

One of the candidate substances, 1-hydroxypropan-2-one [FL-no: 07.169] (acetol), is a metabolite of acetone, which is an endogenous substance formed from the degradation of body fat / fatty acids. The major metabolic pathway in mammals of acetone at low blood concentrations (i.e. in healthy humans not exposed to external sources, acetone occurs in amounts of approximately 4 - 12 mg per person,

corresponding to approximately 0.7 to 2 mg/l blood (Ashley et al., 1994; Dick et al., 1988; Wang et al., 1994c), is via the methylglyoxal route, where acetone is first oxidised to 1-hydroxypropan-2-one, which is then oxidised to 2-oxopropanal (methylglyoxal [FL-no: 07.001]). 2-Oxopropanal will after further metabolism give rise to glucose (Morgott, 1993; WHO, 1998a; NAS/COT, 2005).

Six candidate substances [FL-no: 06.088, 06.090, 06.095, 06.097, 06.102 and 06.135] are acetals, which may be expected to undergo acid catalysed hydrolysis in the gastric environment to yield their component aldehydes and alcohols prior to absorption. Once hydrolysed, the component alcohols and aldehydes are expected to be metabolised primarily through the above mentioned common routes of biotransformations and excreted.

The linear and branched-chain aliphatic primary alcohol components of candidate substances that are simple aliphatic di- and tricarboxylic acid esters would be oxidised in the presence of alcohol dehydrogenase to their corresponding aldehydes which, in turn, would be oxidised to their corresponding carboxylic acids. The two diols [FL-no: 02.132 and 02.198] may be anticipated to participate in the same routes of biotransformation. It may be anticipated that glutaraldehyde [FL-no: 05.149] is biotransformed through the common pathways of detoxication of aldehydes to innocuous products.

Among the candidate substances, an alkoxy-alcohol, 2-butoxyethanol [FL-no: 02.242], is mainly metabolised to butoxyacetic acid, which has been identified as the metabolite responsible for the haemolysis of red blood cells induced by 2-butoxyethanol.

In summary, it can be anticipated that primary and secondary aliphatic saturated or unsaturated alcohols, aldehydes, carboxylic acids, acetals and esters with a second oxygenated functional group and aliphatic lactones included in the present FGE are generally metabolised to innocuous products (many of which are endogenous in humans), at the estimated level of intake as flavouring substances.

The consideration on the actual levels of intake becomes particularly relevant for one candidate substance, diethyl maleate [FL-no: 09.351], as when administered at high doses, it is able to induce severe GSH depletion, due to its prompt metabolism to GSH-conjugates. This may also be the case for the structurally related diethyl fumarate [FL-no: 09.350].

For three of the candidate substances it cannot be concluded that they are metabolised to innocuous products. These are 2-butoxyethan-1-ol [FL-no: 02.242], the major metabolite of which butoxyacetic acid has been recognised as responsible for haematotoxic effects induced by 2-butoxyethanol [FL-no: 02.242], 1,1,3-triethoxypropane [FL-no: 06.097], which may be metabolised to 3-ethoxypropanoic acid, a substance with structural similarities to 2-butoxyethanol and finally, ethyl 2-acetylbutyrate [FL-no: 09.824], of which hydrolysis gives rise to 2-acetylbutyric acid, which shows some structural similarities to valproic acid, a known teratogenic compound.

A more detailed description of the metabolism of the candidate substances in this FGE is given in Annex III.

5. Application of the Procedure for the Safety Evaluation of Flavouring Substances

The application of the Procedure is based on intakes estimated on the basis of the MSDI approach. Where the mTAMDI approach indicates that the intake of a flavouring substance might exceed its corresponding threshold of concern, a formal safety assessment is not carried out using the Procedure. In these cases the Panel requires more precise data on use and use levels. For comparison of the intake estimations based on the MSDI approach and the mTAMDI approach, see Section 6.

For 5-pentyl-3H-furan-2-one [FL-no: 10.170] flavour industry informs that the commercial product is a mixture of two structural isomers – 2/3 is the named compound (5-pentyl-3H-furan-2-one) and 1/3 is the structural isomer - 5-pentyl-5H-furan-2-one. This latter isomer is identical to [FL-no: 10.054], –

which is an alpha,beta-unsaturated alcohol (after hydrolysis of the lactone) allocated FGE.19 subgroup 4.1. This subgroup was evaluated in FGE.217 with the conclusion – additional genotoxicity data required. Therefore, the Panel concluded that [FL-no.10.170] should not be evaluated through the Procedure until these data are available.

In its first evaluation of this group of aliphatic alcohols, aldehydes, acetals, carboxylic acids and esters containing an additional oxygenated functional group and lactones (EFSA, 2005b) the Panel considered that the candidate substance, 1-hydroxypropan-2-one [FL-no: 07.169], should not be evaluated through the Procedure until new data became available because it was found to be genotoxic *in vitro* in bacterial assays. However, in the first revision of FGE.10 (FGE.10Rev1) the Panel reconsidered this compound and concluded that it is an endogenous metabolite of acetone which is formed from the degradation of body fat/fatty acids and that it would be further metabolised to innocuous compounds, and thus not be of concern at the exposure levels resulting from its use as a flavouring substance (see Section 8.4, conclusion on the genotoxicity). The Panel therefore decided that 1-hydroxypropan-2-one [FL-no: 07.169] could be evaluated along the A side of the Procedure in FGE.10Rev1.

For the safety evaluation of the 62 candidate substances in the present revision of FGE.10 the Procedure as outlined in Annex I was applied, based on the MSDI approach. The stepwise evaluations of the substances are summarised in Table 2a.

Step 1

Fifty-five of the candidate substances are classified according to the decision tree approach by Cramer *et al.* (1978) into structural class I, six are classified into structural class II [FL-no: 02.242, 06.088, 06.090, 06.095, 06.097 and 06.135] and one into structural class III [FL-no: 06.102].

Step 2

For three of the candidate substances it cannot be concluded that they are metabolised to innocuous products. These are 2-butoxyethanol [FL-no: 02.242], the major metabolite of which butoxyacetic acid has been recognised as responsible for haematotoxic effects induced by 2-butoxyethanol [FL-no: 02.242], 1,1,3-triethoxypropane [FL-no: 06.097], which may be metabolised to 3-ethoxypropanoic acid, a substance with some structural similarities to 2-butoxyethanol and finally, ethyl 2-acetylbutyrate [FL-no: 09.824], of which hydrolysis gives rise to 2-acetylbutyric acid, which shows some structural similarities to valproic acid, a known teratogenic compound. Therefore, these substances are evaluated via the B-side of the Procedure. The evaluation of the remaining 59 candidate substances proceeds via the A-side of the Procedure.

Step A3

Step A3 applies to 54 candidate substances from structural class I [FL-no: 02.132, 02.198, 05.149, 07.169, 08.053, 08.082, 08.090, 08.103, 08.113, 09.333, 09.345 - 09.354, 09.360, 09.502, 09.558, 09.565, 09.580, 09.590, 09.601, 09.626, 09.629, 09.633, 09.634, 09.644, 09.683, 09.815, 09.832, 09.833, 09.862, 09.874, 09.916, 09.951, 10.038, 10.039, 10.040, 10.045, 10.047 - 10.049, 10.052, 10.055, 10.058, 10.059, 10.063, 10.068 and 10.168], four candidate substances from structural class II [FL-no: 06.088, 06.090, 06.095 and 06.135] and one candidate substance from structural class III [FL-no: 06.102].

The 54 candidate substances which have been assigned to structural class I have estimated European daily *per capita* intakes (MSDI) ranging from 0.0012 to 1500 microgram. The four candidate substances from structural class II have MSDIs ranging from 0.0012 to 1.2 microgram and the one candidate substance assigned to structural class III has an estimated European daily *per capita* intake of 0.011 microgram (Table 6.1). These intakes are below the thresholds of concern of 1800, 540 and 90 microgram/person/day for structural class I, II and III, respectively.

Accordingly, these 59 candidate substances do not pose a safety concern when used at estimated levels of intake as flavouring substances, based on the MSDI approach.

Step B3

The MSDIs of the candidate substances 2-butoxyethan-1-ol [FL-no: 02.242], 1,1,3-triethoxypropane [FL-no: 06.097] and ethyl 2-acetylbutyrate [FL-no: 09.824], were estimated to be 0.0012 microgram/*capita*/day for each. Thus, the MSDI-values of all three candidate substances are below the threshold of concern for their structural classes of 540 microgram/person/day (class II) for [FL-no: 02.242 and 06.097] and of 1800 microgram/person/day (class I) for [FL-no: 09.824]. Accordingly, the three substances proceed to step B4 of the Procedure.

Step B4

The candidate substance ethyl 2-acetylbutyrate [FL-no: 09.824] is expected to be hydrolysed to the corresponding alpha-ethylated carboxylic acid, 2-acetylbutyric acid and ethanol. No toxicity studies that would permit establishing a No Observed Adverse Effect Level (NOAEL) are available for ethyl 2-acetylbutyrate or its hydrolysis product 2-acetylbutyric acid. 2-Acetylbutyric acid is structurally related to 2-ethylhexanol [FL-no: 02.082] for which the JECFA has established an ADI of 0.5 mg/kg bw/day (JECFA, 1993b). The estimated daily *per capita* intake, based on the MSDI approach and expressed in microgram/kg bw/day for the hydrolysis product of the candidate substance ethyl 2-acetylbutyrate (and 2-acetylbutyric acid) is approximately 25×10^6 fold below the acceptable daily intake (ADI) value of the structurally related 2-ethylhexanol. Furthermore, the hydrolysis product, 2-acetylbutyric acid, shows some structural similarities to valproic acid, a known teratogenic compound. If 2-acetylbutyric acid is considered to be as potent as valproic acid (NOAEL = 600 mg/kg bw/day) the margin of safety would be 3×10^9 , based on the MSDI of 0.0012 microgram/*capita*/day. Accordingly, it is concluded that ethyl 2-acetylbutyrate [FL-no: 09.824] does not pose a safety concern at the estimated level of intake, based on the MSDI approach.

For the candidate substances 2-butoxyethan-1-ol [FL-no: 02.242] and 1,1,3-triethoxypropane [FL no: 06.097], the hydrolysis product of which has some structural similarities to 2-butoxyethan-1-ol, a NOAEL could not be established in sub-chronic/chronic toxicity studies with respect to haemotoxicity. Thus, strictly according to the Procedure additional toxicity data would be needed to finalise the evaluation of these two substances in step B4 of the Procedure. However, reconsidering and updating the previous version of this FGE, the Panel noted that at least for 2-butoxyethan-1-ol [FL-no: 02.242] a wealth of toxicity data is available, so that this substance can be evaluated on a broader basis than only the Procedure for the Evaluation of Flavouring substances, which in principle has been designed for the evaluation of data-poor substances.

Considering the data available, especially those on kinetics and mechanism of action (see US-EPA, 1999 and draft EU-RAR 2007, human health part) it becomes clear that there are major differences in sensitivity between humans and rats regarding the prime toxic effect (haemotoxicity) of this substance, with humans (together with dog, guinea pig, pig, cat and rabbit) being considerably less sensitive than rats (together with mouse, hamster and baboon). For that reason it seems inappropriate to ask for further toxicity data in animals, as the available data already cover the most sensitive species. In this case an alternative approach is needed and possible for this data-rich substance (EPA, 1999; EU-RAR, 2007).

In their evaluation, US-EPA, using a Bench Mark Dose approach, combined with physiologically-based kinetic modelling arrived at an oral Reference dose (RfD) for chronic exposure of 0.5 mg/kg body weight (bw)/day (EPA, 1999).

In the EU-RAR (2007) a Human equivalent Lowest Observed Adverse Effect Level (LOAEL) of 9.5 mg/kg bw/day is used, which was derived from the LOAEL in the rat using the same kinetic models as applied by US-EPA. A Margin of Safety of 3 between the Human equivalent LOAEL and estimates

for chronic exposure of "Consumers" or "Humans, exposed via the Environment" was considered sufficient to reach a conclusion of no concern.

For each of the two candidate flavouring substances 2-butoxyethan-1-ol [FL-no: 02.242] and 1,1,3-triethoxypropane [FL no: 06.097] an MSDI of 0.0012 microgram/capita/day (see Table 6.1) can be calculated. The RfD from US-EPA and the LOAEL from the draft EU-RAR are factors of 2.5×10^7 or 4.75×10^8 above the MSDI, respectively. The Panel concluded that these margins are sufficiently large to decide that based on the MSDI exposure estimates, these substances are of no concern when used as flavouring substances.

In conclusion the Panel considered that all candidate substances evaluated through the Procedure were of no safety concern at the estimated levels of intake based on the MSDI approach.

6. Comparison of the Intake Estimations Based on the MSDI Approach and the mTAMDI Approach

The mTAMDI for the 54 candidate substances in structural class I and for which use levels information is available, range from 800 to 5100 microgram/person/day. For 51 of these substances the mTAMDI is above the threshold of concern of 1800 microgram/person/day.

The mTAMDI of the five substances assigned to structural class II, and for which use levels information is available, range from 3800 to 3900 microgram/person/day, which is above the threshold of concern of 540 microgram/person/day.

For the two substances from structural class III the mTAMDI is 3800 and 4100 microgram/person/day, which is above the threshold of 90 microgram/person/day.

Thus, for the 58 candidate substances further information is required as the mTAMDI is above the threshold for the structural class. This would include more reliable intake data and then, if required, additional toxicological data. For two substances [FL-no: 06.135 and 08.113] use levels are required for the food categories as listen in Commission Regulation (EC) No 1565/2000 (EFFA, 2001a; EFFA, 2003c; EFFA, 2003s; EFFA, 2004ag; EFFA, 2007a; Flavour Industry, 2006a; Flavour Industry, 2010g; Flavour Industry, 2010n).

For comparison of the MSDI- and mTAMDI-values see Table 6.1.

Table 6.1 Estimated intakes based on the MSDI approach and the mTAMDI approach

FL-no	EU Register name	MSDI (µg/capita/day)	mTAMDI (µg/person/day)	Structural class	Threshold of concern (µg/person/day)
02.132	Butane-1,3-diol	0.0061	3900	Class I	1800

7. Considerations of Combined Intakes from Use as Flavouring Substances

Because of structural similarities of candidate and supporting substances, it can be anticipated that many of the flavourings are metabolised through the same metabolic pathways and that the metabolites may affect the same target organs. Further, in case of combined exposure to structurally related flavourings, the pathways could be overloaded. Therefore, combined intake should be considered. As flavourings not included in this FGE may also be metabolised through the same pathways, the combined intake estimates presented here are only preliminary. Currently, the combined intake estimates are only based on MSDI exposure estimates, although it is recognised that this may lead to underestimation of exposure. After completion of all FGEs, this issue should be readdressed.

The total estimated combined daily *per capita* intake of structurally related flavourings is estimated by summing the MSDI for individual substances.

As one of the candidate substances, 5-pentyl-3H-furan-2-one [FL-no: 10.170] show possible genotoxic potential *in vitro*, the substance is not taken through the Procedure. This substance is therefore not included in the calculation of the combined intake of the candidate substances evaluated in FGE.10Rev3.

On the basis of the reported annual production volumes in Europe (EFFA, 2000c; EFFA, 2003d; EFFA, 2008b; Flavour Industry, 2010n), the combined estimated daily *per capita* intake as flavourings of the 55 candidate flavouring substances assigned to structural class I is 1600 microgram, of the six candidate flavouring substances assigned to structural class II is 1.2 microgram and of the one candidate substance assigned to structural class III, 0.01 microgram. These estimates do not exceed the thresholds of concern for the corresponding structural classes of 1800, 540 and 90 microgram/person/day, respectively.

The candidate lactones are structurally related to 27⁸ supporting lactones from structural class I, for which the combined intake based on the MSDI approach is approximately 20000 microgram/*capita*/day. The supporting substances were evaluated by the JECFA at the 49th meeting, where it was noted that although the combined intake exceeds the threshold for the structural class, the lactones are expected to be hydrolysed and completely metabolised to innocuous products at the estimated level of intake as flavouring substances, and would not give rise to perturbations outside the physiological range. The Panel agreed with this view and concluded that the additional intake of about 55 microgram/*capita*/day for the candidate lactones is negligible compared to the combined intake of 20000 microgram/*capita*/day of the supporting lactones.

Likewise 41 candidate substances are structurally related to 33⁹ supporting aliphatic primary alcohols and related substances containing an additional oxygenated functional group from structural class I, and for which intake data are available. The combined intake of these supporting substances amounts to approximately 24000 microgram/*capita*/day based on the MSDI approach. These substances were evaluated at the 53rd JECFA meeting, where it was also noted that the substances are expected to be efficiently metabolised to innocuous products and would not give rise to perturbations outside the physiological range. The Panel agreed with this view and concluded that the contribution from the combined intake of the candidate substances of 1540 microgram/*capita*/day would not alter the JECFA conclusion based on a combined intake of 24000 microgram/*capita*/day.

8. Toxicity

8.1. Acute Toxicity

Data are available for 16 of the candidate substances (Annex IV, Table IV.1). For the majority of candidate substances, oral LD₅₀ values, in mice or rats, varied from 100 mg/kg up to more than 5000 mg/kg body weight (bw). For butane-1,3-diol [FL-no: 02.132] and octane-1,3-diol [FL-no: 02.198] LD₅₀ values between 20 g/kg bw and approximately 30 g/kg bw are reported (Annex IV, Table IV.1).

Forty-three supporting substances were tested for acute toxicity in mice and/or rats (Annex IV, Table IV.1). For the majority of the supporting substances, oral LD₅₀ values, in mice or rats, varied from 1300 mg/kg up to 18500 mg/kg bw. For diethyl sebacate [FL-no: 09.475] and tributyl acetyl citrate [FL-no: 09.511] LD₅₀ values larger than 30 g/kg bw are reported.

The acute toxicity data are summarised in Annex IV, Table IV.1.

⁸ European production volumes are only available for 27 of the 29 JECFA evaluated lactones – these substances have been evaluated by JECFA before 2000 and accordingly no EFSA considerations have been performed including requests for production volumes.

⁹ European production volumes are only available for 33 of the 47 JECFA evaluated alcohols and related substances – these substances have been evaluated by JECFA before 2000 and accordingly no EFSA considerations have been performed including requests for production volumes.

8.2. Subacute, Subchronic, Chronic and Carcinogenicity Studies

Subacute/subchronic/chronic toxicity data are available for five candidate substances, 2-butoxyethan-1-ol [FL-no: 02.242], butane-1,3-diol [FL-no: 02.132], malonic acid [FL-no: 08.053], glutaraldehyde [FL-no: 05.149], nonanedioic acid [FL-no: 08.103] and for 20 supporting substances of the present Flavouring Group Evaluation (JECFA, 1998a; JECFA, 2000c). Additionally, data are available for two to succinic acid, disodium salt [FL-no: 08.113] structurally related substances, succinate monosodium and disodium hexahydrate.

Available data on repeated dose toxicity show that haemolysis is the primary and critical response elicited in the main animal test models (rats and mice) following oral exposure to 2-butoxyethan-1-ol, in which the haematotoxic action is produced by the metabolite butoxyacetic acid (this effect is also seen following other exposure routes such as inhalation or dermal exposure. These exposure routes are not considered relevant for this evaluation as data from oral exposure are available). Notably, the haematotoxic effect exhibits a pronounced species difference. In sensitive species (rat, mouse, hamster, baboon), 2-butoxyethan-1-ol produces a characteristic toxicity that is revealed clinically by the appearance of haemoglobinuria and pathologically by changes in a variety of blood parameters (EPA, 1999; EU-RAR, 2004a). Slight decrease in body weight gain, haematological and liver effects have been reported for male and female rats, respectively (NTP, 1993a). Human erythrocytes are about 100-times less sensitive than rat erythrocytes as judged by prehaemolytic changes *in vitro* (increase in mean erythrocyte volume, erythrocyte deformability) consistently observed in both species. Studies have also shown that potentially sensitive human sub-populations, including children, the elderly and those with sickle cell anemia, do not show increased sensitivity to the haemolytic action of 2-butoxyethan-1-ol. Furthermore, the *in vivo* blood concentrations producing haemolysis in the animal experiments are considered unlikely to occur under normal conditions of human exposure to 2-butoxyethan-1-ol (EU-RAR, 2004a).

Carcinogenicity:

In a two year inhalation study, F344/N rats were exposed to 0, 0.031, 0.0625 and 0.125 mg/m³ and B6C3F₁ mice were exposed to 0, 0.0625, 0.125 and 0.250 mg/m³ 2-butoxyethan-1-ol (NTP, 2000b). The exposure caused a low incidence of haemangiosarcoma in male mice at the highest exposure concentration; haemangiosarcoma did not occur in female mice or in rats. In female mice, 2-butoxyethan-1-ol caused an increased incidence of forestomach tumours. It was not carcinogenic in rats. The occurrence of haemangiosarcoma in male mice only at highest exposure concentration is suggestive of a threshold phenomenon, related to the induction of haemolysis in rodent species. With regard to human relevance, the mechanism proposed for the induction of haemangiosarcomas strongly supports the conclusion that 2-butoxyethan-1-ol is unlikely to be a carcinogenic hazard at the estimated level of intake as flavouring substance, because human erythrocytes are demonstrably more resistant to haemolysis than are rodent erythrocytes.

Glutaraldehyde¹⁰ [FL-no: 05.149] (50, 250, 1000 mg/l in drinking water, resulting in doses of 2.9-6.9, 14.5-31.8 and 54.7-104.6 mg/kg/day, respectively) was not tumorigenic in a two year carcinogenicity

¹⁰ Glutaraldehyde is also used in food contact material (FCM). It was evaluated by the former Scientific Committee on Food (SCF List 7, http://europa.eu.int/comm/food/fs/sc/scf/out50_en.pdf), however, this is not a final evaluation. According to German recommendations, glutardialdehyde (synonym: glutaraldehyde) may be used for the production of artificial sausage skin (maximum use level 0.1 %). The maximum residual amount of glutardialdehyde is 50 mg per kg artificial sausage skin (ready for use). Furthermore, glutardialdehyde may be used as anti slime agent for the production of paper as FCM (maximum use level 2.5 % based on dry fibre material). The maximum residual amount of glutardialdehyde is 2 mg per kg paper (ready for use). The Panel noted that maximum residual amounts of glutaraldehyde in food contact material (as set e.g. in German recommendations) could apparently conflict with reported use levels of glutaraldehyde as flavouring. However, in the German recommendations, the maximum residual amounts were set considering the technologically needed use levels (limited data submitted) rather than on toxicological data, and the Panel therefore did not find the low maximum residual amounts for glutaraldehyde as such in conflict with higher use levels for glutaraldehyde as flavouring, which could therefore go through the Procedure.

study on male and female rats (Van Miller et al., 2002). Furthermore, malonic acid [FL-no: 08.053] was negative in a liver foci tumour promotion assay.

Repeated dose toxicity data are summarised in Annex IV, Table IV.2.

8.3. Developmental / Reproductive Toxicity Studies

Data on developmental toxicity and reproductive toxicity are available for the following five candidate substances: 2-butoxyethan-1-ol [FL-no: 02.242], butane-1,3-diol [FL-no: 02.132], glutaric acid [FL-no: 08.082], glutaraldehyde [FL-no: 05.149] and nonanedioic acid [FL-no: 08.103]. Studies for supporting substances comprise butyro-1,4-lactone [FL-no: 10.006] and adipic acid [FL-no: 08.026] (JECFA, 1998a; JECFA, 2000c) and one structurally related substance, succinate disodium hexahydrate (Annex IV, Table IV.3).

For 2-butoxyethan-1-ol [FL-no: 02.242] no effects on fertility were observed in female and male mice given 2-butoxyethan-1-ol in the drinking water in a continuous breeding study in which a NOAEL of 720 mg/kg was derived (EU-RAR, 2004a). As to developmental toxicity, studies performed on animals via various administration routes did not demonstrate any teratogenic potential, and foetotoxicity and embryotoxicity (lethality and resorptions) were only observed in the presence of maternal toxicity (regenerative haemolytic anaemia). Other effects seen on foetuses were an increase in the incidence of skeletal variations, which are generally described as ossification delays. The effects seen in developmental toxicity studies with 2-butoxyethan-1-ol are considered to result from haemolysis and subsequent maternal anemia (EU-RAR, 2004a). Overall, 2-butoxyethan-1-ol is not considered to pose a safety concern with respect to reproduction and development at the estimated level of intake as flavouring substance.

No information is available on ethyl 2-acetyl butyrate [FL-no: 09.824], the hydrolysis product of which, 2-acetyl butyric acid, has some structural similarities to valproic acid, which, together with a number of its derivatives, has been recognised as teratogenic in rodents and in humans (Nau and Löscher, 1986; Samren et al., 1997; Kaneko et al., 1999). Offspring of mothers using > 1000 mg/kg bw/day valproic acid per day were at a significantly increased risk of major congenital malformations especially neural tube defects, compared to offspring exposed < or 600 mg valproic acid/day (RR 6.8; 95 % CI: 1.4 - 32.7). No difference in risk of major congenital malformations was found between the offspring exposed to 601 - 1000 mg/day and < or = 600 mg/kg bw/day. Thus, 600 mg/day is considered as NOAEL for the teratogenic effects of valproic acid in humans.

Developmental/reproductive toxicity data are summarised in Annex IV, Table IV.3.

8.4. Genotoxicity Studies

Genotoxicity data were provided for 12 of the candidate substances. These 12 substances are pentano-1,5-lactone [FL-no: 10.055], 5,6-dimethyl-tetrahydro-pyran-2-one [FL-no: 10.168], glutaraldehyde [FL-no: 05.149], 1-hydroxypropan-2-one [FL-no: 07.169], butane-1,3-diol [FL-no: 02.132], malonic acid [FL-no: 08.053], diethyl maleate [FL-no: 09.351], diethyl adipate [FL-no: 09.348], methyl acetoacetate [FL-no: 09.634], 2-butoxyethan-1-ol [FL-no: 02.242], glutaric acid [FL-no: 08.082] and succinic acid, disodium salt [FL-no: 08.113]. There were genotoxicity data on 22 supporting substances and for one structurally related substance (Annex IV, Table IV.4 and IV.5).

For 5-pentyl-3H-furan-2-one [FL-no: 10.170] flavour industry informs that the commercial product is a mixture of two structural isomers – 2/3 is the named compound (5-pentyl-3H-furan-2-one) and 1/3 is the structural isomer - 5-pentyl-5H-furan-2-one. This latter isomer is identical to [FL-no: 10.054], which is an alpha,beta-unsaturated alcohol (after hydrolysis of the lactone) allocated to FGE.19 subgroup 4.1. This subgroup was evaluated in FGE.217 with the conclusion that additional

genotoxicity data required. Therefore, the Panel concluded that [FL-no: 10.170] should not be evaluated through the Procedure until these data are available.

In vitro

Pentano-1,5-lactone [FL-no: 10.055], 5,6-dimethyl-tetrahydro-pyran-2-one [FL-no: 10.168] methyl acetoacetate [FL-no: 09.634] and succinic acid [FL-no: 08.113] were reported to be negative in microbial mutagenicity assays.

1-Hydroxypropan-2-one [FL-no: 07.169] was positive in Ames tests using strains TA 100 and TA 104 in the presence and absence of S-9 metabolic activation (Garst et al., 1983; Marnett et al., 1985a; Yamaguchi, 1982; Yamaguchi and Nakagawa, 1983). These results are consistent across the four reported studies which, despite limitations in study design and reporting, suggest that 1-hydroxypropan-2-one should be considered an *in vitro* mutagen in bacteria. There are no data provided on either *in vitro* endpoints nor on *in vivo* studies.

Diethyl maleate [FL-no: 09.351] was reported to produce mutations in the TK +/- locus of L5178Y mouse lymphoma cells. However, the concentration required for a two-fold increase of mutations results in 70 % growth reduction (Wangenheim and Bolcsfoldi, 1988), rendering this effect questionable. Diethyl maleate was positive in an aneuploidy test using V79 Chinese hamster lung cells at 8.7×10^{-6} M but not at 5.2×10^{-6} M (Önfelt, 1987); generally aneuploidy is considered as a threshold phenomenon.

In vitro and/or in vivo

Glutaric acid [FL-no: 08.082] was reported to be negative in the Ames and Rec test as well as in an *in vivo* test for rat bone marrow aberrations.

2-Butoxyethan-1-ol [FL no: 02.242] was negative in the Ames test and in *in vitro* tests in mammalian cells for induction of forward mutations, chromosomal aberrations and sister chromatid exchanges (SCE). Positive results were only reported in one study in V79 cells (for induction of forward mutations, SCE and micronuclei) at doses above the maximum level recommended by current OECD Guidelines. Equivocal positive results were reported in an unscheduled DNA synthesis (UDS) assay in primary rat hepatocytes. *In vivo*, negative results were obtained in an adequate micronucleus tests in rats and mice following oral or intraperitoneal administration. No evidence of DNA binding or alteration of DNA methylation was obtained in a study in rats and mice. The overall experimental evidence indicated that 2-butoxyethan-1-ol is not genotoxic (see Table IV.5).

Glutaraldehyde [FL-no: 05.149] exhibits genotoxic effects in *in vitro* tests, most consistently in the bacterial mutagenicity assays. Forward gene mutation tests *in vitro* in mammalian cells have given variable results depending on the locus: negative with HGPRT and positive with TK. Also, SCE, chromosome aberration and UDS tests have shown no effect to a weakly positive effect, depending on the laboratory, protocol, dosages and sampling times. However, that any *in vitro* potential for genotoxic effects will not be expressed *in vivo* is indicated by the *in vivo* study results, which include chromosomal aberrations, mammalian erythrocyte micronucleus test, UDS and recessive lethal mutations. The only study suggesting an *in vivo* effect was an increase in micronuclei in mouse blood cells up to 15 mg/kg bw. However, the data are insufficiently reported. The negative results from the well-conducted *in vivo* studies may be related to the rapid metabolism and protein binding characteristics of glutaraldehyde, and the related observation that although ¹⁴C-labelled glutaraldehyde may be detected in cell cytoplasm there is no nuclear fraction radioactivity (Vergnes and Ballantyne, 2002).

Butane-1,3-diol [FL-no: 02.132] was reported as not inducing chromosomal aberration in bone marrow and was negative in a rat dominant lethal assay. Butane-1,3-diol [FL-no: 02.132] was checked for cytogenetic effects over a period of three generations at doses of 5 % (5000 mg/kg/day), 10 % and

24 %. None of the doses produced abnormal rates of bone marrow metaphase cells as compared to controls (Hess et al., 1981).

Malonic acid [FL-no: 08.053] was found negative in a rat liver foci assay, diethyl adipate [FL-no: 09.348] was reported to be negative in a mouse dominant lethal assay.

Genotoxicity tests are available for 22 supporting substances. Some positive test results from *in vitro* studies are reported for 4-hydroxybutyric acid lactone [FL-no: 10.006], which, however, was found negative in a reliable *Drosophila in vivo* sex-linked recessive lethal mutation assay (Table IV 4 and 5). Results of *in vivo* bone marrow micronucleus assays in mice available for 4-hydroxybutyric acid lactone were also negative, however, since the PCE/NCE ratio was not reported it is not clear if the test substance reached the bone marrow (Table IV.5). Positive *in vitro* data that cannot be evaluated are reported for hexano-1,5-lactone [FL-no: 10.010], nonano-1,4-lactone [FL-no: 10.001], undecano-1,4-lactone [FL-no: 10.002], undecano-1,5-lactone [FL-no: 10.011] and ethyl acetoacetate [FL-no: 09.402] (Annex IV, Table IV.4).

Conclusions on genotoxicity

Genotoxicity data are only available on a very limited number of the candidate substances in this Flavouring Group Evaluation and none has a complete package of mutagenicity endpoints.

One of the candidate substances (1-hydroxypropan-2-one [FL-no: 07.169]) induced gene mutations in bacteria but has not been studied *in vivo* or in other *in vitro* assays.

In its first evaluation of this group of aliphatic alcohols, aldehydes, acetals, carboxylic acids and esters containing an additional oxygenated functional group and lactones (EFSA, 2005b) the Panel considered that for the candidate substance, 1-hydroxypropan-2-one [FL-no: 07.169], it was necessary to request additional *in vitro* data from studies in mammalian cells. However, in the first revision of FGE.10 (FGE.10Rev1) the Panel reconsidered the fact that 1-hydroxypropan-2-one is an endogenous metabolite of acetone. Acetone is endogenously formed from the degradation of body fat/fatty acids and occurs in the blood of healthy humans not exposed to external sources of acetone in amounts of approximately 4 - 12 mg/person corresponding to 0.7 to 2 mg/l blood. Under these conditions, the majority of the acetone in blood would be metabolised to 1-hydroxypropan-2-one, which is rapidly further metabolised to endogenous compounds (methylglyoxal, pyruvate and glucose) in the methylglyoxal pathway. The estimated exposure of 0.22 microgram/capita/day is considerably lower than that resulting from the metabolism of acetone and would not significantly add to the internal exposure to 1-hydroxypropan-2-one in the body and would not perturb the normal catabolism of the compound to innocuous endogenous products. The Panel therefore concluded that 1-hydroxypropan-2-one [FL-no: 07.169] would not be of safety concern at the exposure level resulting from its use as a flavouring substance. Consequently, the Panel decided that further studies on the *in vitro* genotoxicity of 1-hydroxypropan-2-one [FL-no: 07.169] would not be required.

Glutaraldehyde was tested *in vitro* and *in vivo*, with positive findings *in vitro*. However, based upon the negative results of *in vivo* genotoxicity assays, along with the lack of tumorigenicity in mice and rats, the *in vitro* genotoxicity data are not considered relevant for the safety evaluation of glutaraldehyde.

Disodium succinate [FL-no: 08.113] did not induce mutations in bacterial reverse mutation assays using *S.typhimurium* strains TA97, TA94, TA98, TA100, TA1535, and TA1537 at 5 mg/plate (with metabolic activation) and in TA97 and TA102 at 15 mg/plate (with or without metabolic activation). A chromosomal test with Chinese hamster lung (CHL) cells revealed equivocal effects on polyploidy at 15 mg/mL (Ishidate et al., 1984; Fujita et al., 1994; OECD, 2003). These results are supported by studies on disodium succinate hexahydrate.

5-pentyl-3H-furan-2-one [FL-no: 10.170] should not be evaluated through the Procedure until the additional genotoxicity data for FL-no: 10.054 are available, as stated in FGE 217.

The available experimental data indicate that 2-butoxyethan-1-ol is not genotoxic.

For the remaining candidate substances, the genotoxic potential cannot be assessed adequately, however, from the limited data available there were no indications that genotoxicity for these substances should give rise to safety concern.

Genotoxicity data are summaries in Annex IV, Table IV.4 and Table IV.5.

9. Conclusions

The candidate substances are alcohols, aldehydes, acetals, carboxylic acids and esters containing additional oxygenated functional groups and lactones.

The present revision of FGE.10, FGE.10Rev3, includes the assessment of two additional candidate substances [FL-no: 09.951 and 10.170].

Thirty-six of the candidate substances possess one or more chiral centres and eight can exist as geometrical isomers due to the presence and the position of a double bond. For four of these eight substances [FL-no: 10.038, 10.040, 10.059 and 10.063] the stereoisomeric composition has not been specified sufficiently. For [FL-no: 10.170] the Industry has informed that the commercial substance is a mixture of two structural isomers. One of these isomers possesses a chiral centre for which the configuration has not been specified.

Fifty-five of the candidate substances belong to structural class I, six of the candidate substances belong to structural class II, and two belong to structural class III according to the decision tree approach presented by Cramer et al. (1978).

Fifty of the flavouring substances in the present group have been reported to occur naturally in a wide range of food items.

The candidate substances which have been assigned to structural class I have estimated European daily *per capita* intakes (MSDI) ranging from 0.0012 to 1500 microgram. The candidate substances from structural class II have MSDIs ranging from 0.0012 to 1.2 microgram and the two candidate substances assigned to structural class III have estimated European daily *per capita* intakes of 0.011 and 1.2 microgram (Table 6.1). These intakes are below the thresholds of concern of 1800, 540 and 90 microgram/person/day for structural class I, II and III, respectively.

The combined estimated daily *per capita* intake as flavourings of the 55 candidate substances assigned to structural class I is 1600 microgram, which does not exceed the threshold of concern for a substance belonging to structural class I of 1800 microgram/person/day. Likewise, the combined estimated daily *per capita* intake as flavouring of the six candidate substances assigned to structural class II is 1.2 microgram, which does not exceed the threshold of concern for a substance belonging to structural class II of 540 microgram/person/day.

The candidate lactones are structurally related to 27 supporting lactones from structural class I, for which the combined intake based on the MSDI approach is approximately 20000 microgram/capita/day. The supporting substances were evaluated by JECFA at the 49th meeting, where it was noted that although the combined intake exceeds the threshold for the structural class, the lactones are expected to be hydrolysed and completely metabolised to innocuous products at the estimated level of intake as flavouring substances, and would not give rise to perturbations outside the physiological range. The Panel agreed with this view and concluded that the additional intake of about 55 microgram/capita/day for the candidate lactones is negligible compared to the combined intake of 20000 microgram/capita/day of the supporting lactones.

Likewise 41 candidate substances are structurally related to 33 supporting aliphatic primary alcohols and related substances containing an additional oxygenated functional group from structural class I, and for which intake data are available. The combined intake of these supporting substances amounts to approximately 24000 microgram/*capita*/day based on the MSDI approach. These substances were evaluated at the 53rd JECFA meeting, where it was also noted that the substances are expected to be efficiently metabolised to innocuous products and would not give rise to perturbations outside the physiological range. The Panel agreed with this view and concluded that the contribution from the combined intake of the candidate substances of 1540 microgram/*capita*/day would not alter the JECFA conclusion based on a combined intake of 24000 microgram/*capita*/day.

For 5-pentyl-3H-furan-2-one [FL-no: 10.170], the flavour Industry informs that the commercial product is a mixture of two structural isomers – 2/3 is the named compound (5-pentyl-3H-furan-2-one) and 1/3 is the structural isomer - 5-pentyl-5H-furan-2-one. This latter isomer is identical to [FL-no: 10.054], which is an alpha, beta-unsaturated alcohol (after hydrolysis of the lactone), allocated to subgroup 4.1 of FGE.19 (FGE.217). The Panel concluded that 5-pentyl-3H-furan-2-one [FL-no: 10.170] should not be evaluated through the Procedure until the additional genotoxicity data for [FL-no: 10.054] are available, as stated in FGE 217.

The Panel reconsidered the fact that 1-hydroxypropan-2-one [FL-no: 07.169] is an endogenous metabolite of acetone. Acetone is endogenously formed from the degradation of body fat/fatty acids and occurs in the blood of healthy humans not exposed to external sources of acetone in amounts of approximately 4 - 12 mg/person corresponding to 0.7 to 2 mg/l blood. Under these conditions, the majority of the acetone in blood would be metabolised to 1-hydroxypropan-2-one, which is rapidly further metabolised to endogenous compounds (methylglyoxal, pyruvate and glucose) in the methylglyoxal pathway. The estimated exposure of 0.22 microgram/*capita*/day is considerably lower than that resulting from the metabolism of acetone and would not significantly add to the internal exposure to 1-hydroxypropan-2-one in the body and would not perturb the normal catabolism of the compound to innocuous endogenous products. The Panel therefore decided that further genotoxicity data are not required and that the substance could be taken through the Procedure.

For the remaining candidate substances, the genotoxic potential cannot be assessed adequately, however, from the limited data available there were no indications that genotoxicity for these substances should give rise to safety concern.

It can be anticipated that, at the estimated levels of intake as flavouring substances, the alcohols, aldehydes, acetals, carboxylic acids and esters with an additional oxygenated functional group and aliphatic lactones included in the present FGE are generally hydrolysed and completely metabolised to innocuous products, many of which are endogenous in humans. The consideration on the actual levels of intake becomes particularly relevant for one candidate substance, diethyl maleate [FL-no: 09.351], as when administered at high doses, it is able to induce severe GSH depletion, due to its prompt metabolism to GSH-conjugates. This may also be the case for the structurally related diethyl fumarate [FL-no: 09.350]. However, as the estimated levels of intake as flavouring substances are sufficiently low for these two substances, profound GSH depletion is not expected. For three of the candidate substances it cannot be concluded that they are metabolised to innocuous products. These are 2-butoxyethanol [FL-no: 02.242], the major metabolite of which butoxyacetic acid has been recognised as responsible for haematotoxic effects induced by 2-butoxyethanol [FL-no: 02.242], 1,1,3-triethoxypropane [FL-no: 06.097], which may be metabolised to 3-ethoxypropanoic acid, a substance which has structural similarities to 2-butoxyethanol and finally, ethyl 2-acetylbutyrate [FL-no: 09.824], of which hydrolysis gives rise to 2-acetylbutyric acid, which shows some structural similarities to valproic acid, a known teratogenic compound. Adequate margins of safety could be established for these three substances in step B4 of the Procedure.

Otherwise, it was noted that where toxicity data were available they were consistent with the conclusions in the present Flavouring Group Evaluation using the Procedure.

It was considered that on the basis of the default MSDI approach that the 62 flavouring substances, to which the Procedure have been applied, would not give rise to safety concerns at the estimated levels of intake arising from their use as flavouring substances.

The mTAMDI for the 54 candidate substances in structural class I, for which use levels information is available, range from 800 to 5100 microgram/person/day. For 51 of these substances the mTAMDI is above the threshold of concern of 1800 microgram/person/day. The mTAMDI of the five substances assigned to structural class II, and for which use levels information is available, range from 3800 to 3900 microgram/person/day, which is above the threshold of concern of 540 microgram/person/day. For the two substances from structural class III the mTAMDI are 3800 and 4100, which is above the threshold of 90 microgram/person/day. For two substances [FL-no: 06.135 and 08.113] no use levels have been provided for the food categories as listed in Commission Regulation (EC) No 1565/2000.

Thus, for 60 candidate substances further information is required. This would include more reliable intake data and then, if required, additional toxicological data. The three candidate substances [FL-no: 05.149, and 07.169 and 09.951] which have mTAMDI intake estimates below the threshold of concern for structural class I are also expected to be metabolised to innocuous products.

Thus, in conclusion, 62 of the 63 flavouring substances were evaluated through the Procedure (based on MSDI approach), as one flavouring substance, 5-pentyl-3H-furan-2-one [FL-no: 10.170] could not be evaluated through the Procedure until adequate genotoxicity data become available.

In order to determine whether the conclusion for the 62 candidate substances, which have been evaluated using the Procedure, can be applied to the materials of commerce, it is necessary to consider the available specifications. Specifications including complete purity criteria and identity for the materials of commerce have been provided for 58 flavouring substances. For four substances [FL-no: 10.038, 10.040, 10.059 and 10.063] information on composition of mixture and/or stereoisomerism has not been specified sufficiently. For one substance [FL-no: 10.063] an identity test is missing. Thus, the final evaluation of the materials of commerce cannot be performed for four substances [FL-no: 10.038, 10.040, 10.059 and 10.063], pending further information.

For the remaining 58 candidate substances [FL-no: 02.132, 02.198, 02.242, 05.149, 06.088, 06.090, 06.095, 06.097, 06.102, 06.135, 07.169, 08.053, 08.082, 08.090, 08.103, 08.113, 09.333, 09.345 - 09.354, 09.360, 09.502, 09.558, 09.565, 09.580, 09.590, 09.601, 09.626, 09.629, 09.633, 09.634, 09.644, 09.683, 09.815, 09.824, 09.832, 09.833, 09.862, 09.874, 09.916, 09.951, 10.039, 10.045, 10.047 - 10.049, 10.052, 10.055, 10.058, 10.068 and 10.168] the Panel concluded that they would present no safety concern at the estimated levels of intake based on the MSDI approach.

10.170	5-Pentyl-3H-furan-2-one	  Commercial compound: 66% of the 3H-isomer 33% of the 5H-isomer	1.2	Class III No evaluation			a)

- 1) EU MSDI: Amount added to food as flavour in (kg / year) x 10E9 / (0.1 x population in Europe (= 375 x 10E6) x 0.6 x 365) = µg/capita/day.
- 2) Thresholds of concern: Class I = 1800 µg/person/day, Class II = 540 µg/person/day, Class III = 90 µg/person/day.
- 3) Procedure path A substances can be predicted to be metabolised to innocuous products. Procedure path B substances cannot.
- 4) No safety concern based on intake calculated by the MSDI approach of the named compound.
- 5) Data must be available on the substance or closely related substances to perform a safety evaluation.
- 6) No safety concern at estimated level of intake of the material of commerce meeting the specification of Table 1 (based on intake calculated by the MSDI approach).

- 7) Tentatively regarded as presenting no safety concern (based on intake calculated by the MSDI approach) pending further information on the purity of the material of commerce and/or information on stereoisomerism.
- 8) No conclusion can be drawn due to lack of information on the purity of the material of commerce.
 - a) 1/3 of the named compound correspond to FL-no: 10.054 which is included in FGE.217: additional genotoxicity data required.

10.014	Nonano-1,5-lactone		3356 2194 3301-94-8	230 JECFA specification (JECFA, 1998b)	130	No safety concern c) Category B b)	JECFA evaluated hydroxynonanoic acid delta-lactone (CASrn as in Register). Register CASrn refers to the racemate.
10.015	Octano-1,5-lactone		3214 2195 698-76-0	228 JECFA specification (JECFA, 2000d)	230	No safety concern c) Category B b)	JECFA evaluated delta-octalactone (CASrn as in Register). Register CASrn refers to the racemate.
10.016	Tetradecano-1,5-lactone		3590 2196 2721-22-4	238 JECFA specification (JECFA, 1998b)	110	No safety concern c) Category B b)	JECFA evaluated delta-tetradecalactone (CASrn as in Register). (R)- or (S)- enantiomer not specified by Register CASrn.
10.017	Decano-1,4-lactone		2360 2230 706-14-9	231 JECFA specification (JECFA, 1998b)	1600	No safety concern c) Category A b)	JECFA evaluated gamma-decalactone (CASrn as in Register). Register CASrn refers to the racemate.
10.018	4-Butyloctano-1,4-lactone		2372 2231 7774-47-2	227 JECFA specification (JECFA, 2000d)	0.12	No safety concern c) Deleted b)	Deleted CoE: the CoE Committee of Experts had no information as to the real use in foodstuffs and/or for which insufficient technological and/or toxicological information was available (CoE, 1992).
10.019	Dodecano-1,4-lactone		2400 2240 2305-05-7	235 JECFA specification (JECFA, 1998b)	190	No safety concern c) Category A b)	JECFA evaluated gamma-dodecalactone (CASrn as in Register). Register CASrn refers to the racemate.
10.020	Heptano-1,4-lactone		2539 2253 105-21-5	225 JECFA specification (JECFA, 2000d)	170	No safety concern c) Category A b)	JECFA evaluated gamma-heptalactone (CASrn as in Register). Register CASrn refers to the racemate.
10.021	Hexano-1,4-lactone		2556 2254 695-06-7	223 JECFA specification (JECFA, 1998b)	160	No safety concern c) Category A b)	JECFA evaluated gamma-hexalactone (CASrn as in Register). Register CASrn refers to the racemate.

Table 3: Supporting Substances Summary

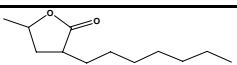

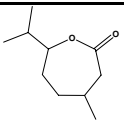

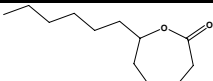

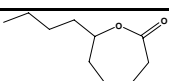

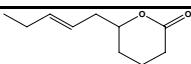

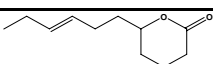

FL-no	EU Register name	Structural formula	FEMA no CoE no CAS no	JECFA no Specification available	MSDI (EU) 1 (µg/capita/day)	SCF status 2) JECFA status 3) CoE status 4)	Comments
10.022	Octano-1,4-lactone		2796 2274 104-50-7	226 JECFA specification (JECFA, 2000d)	430	No safety concern c) Category A b)	the racemate. JECFA evaluated gamma-octalactone (CASrn as in Register). Register CASrn refers to the racemate.
10.026	3-Heptyldihydro-5-methyl-2(3H)-furanone		3350 10953 40923-64-6	244 JECFA specification (JECFA, 2003b)	0.037	No safety concern c)	JECFA evaluated 3-heptyldihydro-5-methyl-2(3H)-furanone (CASrn as in Register). (R)- or (S)-enantiomer not specified by Register CASrn.
10.027	3,7-Dimethyloctano-1,6-lactone		3355 11833 499-54-7	237 JECFA specification (JECFA, 2003b)	0.012	No safety concern c)	JECFA evaluated 6-hydroxy-3,7-dimethyloctanoic acid lactone (CASrn as in Register). (R)- or (S)-enantiomer not specified by Register CASrn.
10.028	Dodecano-1,6-lactone		3610 16429-21-3	242 JECFA specification (JECFA, 2000d)	0.012	No safety concern c)	JECFA evaluated epsilon-dodecalactone (CASrn as in Register). (R)- or (S)- enantiomer not specified by Register CASrn.
10.029	Decano-1,6-lactone		3613 5579-78-2	241 JECFA specification (JECFA, 2000d)	0.012	No safety concern c)	JECFA evaluated epsilon-decalactone (CASrn as in Register). (R)- or (S)- enantiomer not specified by Register CASrn.
10.033	Dec-7-eno-1,5-lactone		3745 34686-71-0	247 JECFA specification (JECFA, 2000d)	0.22	No safety concern c)	JECFA evaluated 5-Hydroxy-7-decenoic acid delta-lactone (CASrn 25524-95-2 which refers to the (Z)-isomer). Neither (Z)- or (E)-isomer nor (R)- or (S)-enantiomer specified by Register CASrn.
10.035	Undec-8-eno-1,5-lactone		3758 68959-28-4	248 JECFA specification (JECFA, 2000d)	0.012	No safety concern c)	JECFA evaluated 5-hydroxy-8-undecenoic acid delta-lactone (CASrn as in Register). (R)- or (S)-enantiomer

Table 3: Supporting Substances Summary

FL-no	EU Register name	Structural formula	FEMA no CoE no CAS no	JECFA no Specification available	MSDI (EU) 1) (µg/capita/day)	SCF status 2) JECFA status 3) CoE status 4)	Comments
10.051	5-Hexyl-5-methyldihydrofuran-2(3H)-one		3786 7011-83-8	250 JECFA specification (JECFA, 1998b)	ND	No safety concern c)	not specified by Register CASrn. JECFA evaluated gamma-methyldecalactone (CASrn as in Register). (R)- or (S)- enantiomer not specified by Register CASrn.
10.053	3-Methyloctano-1,4-lactone		3803 10535 39212-23-2	437 JECFA specification (JECFA, 1998b)	ND	No safety concern c)	JECFA evaluated 4-hydroxy-3-methyloctanoic acid gamma-lactone (CASrn as in Register). (R)- or (S)-enantiomer not specified by Register CASrn.

1) EU MSDI: Amount added to food as flavouring substance in (kg / year) x 10E9 / (0.1 x population in Europe (= 375 x 10E6) x 0.6 x 365) = µg/capita/day.

2) Category 1: Considered safe in use, Category 2: Temporarily considered safe in use, Category 3: Insufficient data to provide assurance of safety in use, Category 4: Not acceptable due to evidence of toxicity.

3) No safety concern at estimated levels of intake.

4) Category A: Flavouring substance, which may be used in foodstuffs, Category B: Flavouring substance which can be used provisionally in foodstuffs.

a) (JECFA, 2000b).

b) (CoE, 1992).

c) (JECFA, 1999b).

d) (JECFA, 2000c).

ND No intake data reported.

ANNEX I: PROCEDURE FOR THE SAFETY EVALUATION

The approach for a safety evaluation of chemically defined flavouring substances as referred to in Commission Regulation (EC) No 1565/2000 (EC, 2000a), named the "Procedure", is shown in schematic form in Figure I.1. The Procedure is based on the Opinion of the Scientific Committee on Food expressed on 2 December 1999 (SCF, 1999a), which is derived from the evaluation Procedure developed by the Joint FAO/WHO Expert Committee on Food Additives at its 44th, 46th and 49th meetings (JECFA, 1995; JECFA, 1996a; JECFA, 1997a; JECFA, 1999b).

The Procedure is a stepwise approach that integrates information on intake from current uses, structure-activity relationships, metabolism and, when needed, toxicity. One of the key elements in the Procedure is the subdivision of flavourings into three structural classes (I, II, III) for which thresholds of concern (human exposure thresholds) have been specified. Exposures below these thresholds are not considered to present a safety concern.

Class I contains flavourings that have simple chemical structures and efficient modes of metabolism, which would suggest a low order of oral toxicity. Class II contains flavourings that have structural features that are less innocuous, but are not suggestive of toxicity. Class III comprises flavourings that have structural features that permit no strong initial presumption of safety, or may even suggest significant toxicity (Cramer et al., 1978). The thresholds of concern for these structural classes of 1800, 540 or 90 microgram/person/day, respectively, are derived from a large database containing data on subchronic and chronic animal studies (JECFA, 1996a).

In Step 1 of the Procedure, the flavourings are assigned to one of the structural classes. The further steps address the following questions:

- can the flavourings be predicted to be metabolised to innocuous products¹¹ (Step 2)?
- do their exposures exceed the threshold of concern for the structural class (Step A3 and B3)?
- are the flavourings or their metabolites endogenous¹² (Step A4)?
- does a NOAEL exist on the flavourings or on structurally related substances (Step A5 and B4)?

In addition to the data provided for the flavouring substances to be evaluated (candidate substances), toxicological background information available for compounds structurally related to the candidate substances is considered (supporting substances), in order to assure that these data are consistent with the results obtained after application of the Procedure.

The Procedure is not to be applied to flavourings with existing unresolved problems of toxicity. Therefore, the right is reserved to use alternative approaches if data on specific flavourings warranted such actions.

¹¹ "Innocuous metabolic products": Products that are known or readily predicted to be harmless to humans at the estimated intakes of the flavouring agent" (JECFA, 1997a).

¹² "Endogenous substances": Intermediary metabolites normally present in human tissues and fluids, whether free or conjugated; hormones and other substances with biochemical or physiological regulatory functions are not included (JECFA, 1997a).

Procedure for Safety Evaluation of Chemically Defined Flavouring Substances

Figure I.1 Procedure for Safety Evaluation of Chemically Defined Flavouring Substances

1 ANNEX II: USE LEVELS / MTAMDI

2 II.1 Normal and Maximum Use Levels

3 For each of the 18 Food categories (Table II.1.1) in which the candidate substances are used, Flavour
4 Industry reports a “normal use level” and a “maximum use level” (EC, 2000a). According to the Industry the
5 “normal use” is defined as the average of reported usages and “maximum use” is defined as the 95th
6 percentile of reported usages (EFFA, 2002i). The normal and maximum use levels in different food
7 categories have been extrapolated from figures derived from 12 model flavouring substances (EFFA, 2004e).

Table II.1.1 Food categories according to Commission Regulation (EC) No 1565/2000 (EC, 2000a)

Food category	Description
01.0	Dairy products, excluding products of category 02.0
02.0	Fats and oils, and fat emulsions (type water-in-oil)
03.0	Edible ices, including sherbet and sorbet
04.1	Processed fruit
04.2	Processed vegetables (incl. mushrooms & fungi, roots & tubers, pulses and legumes), and nuts & seeds
05.0	Confectionery
06.0	Cereals and cereal products, incl. flours & starches from roots & tubers, pulses & legumes, excluding bakery
07.0	Bakery wares
08.0	Meat and meat products, including poultry and game
09.0	Fish and fish products, including molluscs, crustaceans and echinoderms
10.0	Eggs and egg products
11.0	Sweeteners, including honey
12.0	Salts, spices, soups, sauces, salads, protein products, etc.
13.0	Foodstuffs intended for particular nutritional uses
14.1	Non-alcoholic (“soft”) beverages, excl. dairy products
14.2	Alcoholic beverages, incl. alcohol-free and low-alcoholic counterparts
15.0	Ready-to-eat savouries
16.0	Composite foods (e.g. casseroles, meat pies, mincemeat) - foods that could not be placed in categories 01.0 - 15.0

8 The “normal and maximum use levels” are provided by Industry for 61 of the candidate substances in the
9 present Flavouring Group Evaluation (Table II.1.2) (EFFA, 2001a; EFFA, 2003c; EFFA, 2003s; EFFA,
10 2004ag; EFFA, 2007a; Flavour Industry, 2006a; Flavour Industry, 2010g; Flavour Industry, 2010n).

II.2 mTAMDI Calculations

The method for calculation of modified Theoretical Added Maximum Daily Intake (mTAMDI) values is based on the approach used by SCF up to 1995 (SCF, 1995). The assumption is that a person may consume the amount of flavourable foods and beverages listed in Table II.2.1. These consumption estimates are then multiplied by the reported use levels in the different food categories and summed up.

Table II.2.1 Estimated amount of flavourable foods, beverages, and exceptions assumed to be consumed per person per day (SCF, 1995)

Class of product category	Intake estimate (g/day)
Beverages (non-alcoholic)	324.0
Foods	133.4
Exception a: Candy, confectionery	27.0
Exception b: Condiments, seasonings	20.0

Table II.2.1 Estimated amount of flavourable foods, beverages, and exceptions assumed to be consumed per person per day (SCF, 1995)

Class of product category	Intake estimate (g/day)
Exception c: Alcoholic beverages	20.0
Exception d: Soups, savouries	20.0
Exception e: Others, e.g. chewing gum	e.g. 2.0 (chewing gum)

The mTAMDI calculations are based on the normal use levels reported by Industry. The seven food categories used in the SCF TAMDI approach (SCF, 1995) correspond to the 18 food categories as outlined in Commission Regulation (EC) No 1565/2000 (EC, 2000a) and reported by the Flavour Industry in the following way (see Table II.2.2):

- Beverages (SCF, 1995) correspond to food category 14.1 (EC, 2000a)
- Foods (SCF, 1995) correspond to the food categories 1, 2, 3, 4.1, 4.2, 6, 7, 8, 9, 10, 13, and/or 16 (EC, 2000a)
- Exception a (SCF, 1995) corresponds to food category 5 and 11 (EC, 2000a)
- Exception b (SCF, 1995) corresponds to food category 15 (EC, 2000a)
- Exception c (SCF, 1995) corresponds to food category 14.2 (EC, 2000a)
- Exception d (SCF, 1995) corresponds to food category 12 (EC, 2000a)
- Exception e (SCF, 1995) corresponds to others, e.g. chewing gum.

Table II.2.2 Distribution of the 18 food categories listed in Commission Regulation (EC) No 1565/2000 (EC, 2000a) into the seven SCF food categories used for TAMDI calculation (SCF, 1995)

Food categories according to Commission Regulation (EC) No1565/2000		Distribution of the seven SCF food categories		
Key	Food category	Food	Beverages	Exceptions
01.0	Dairy products, excluding products of category 02.0	Food		
02.0	Fats and oils, and fat emulsions (type water-in-oil)	Food		
03.0	Edible ices, including sherbet and sorbet	Food		
04.1	Processed fruit	Food		
04.2	Processed vegetables (incl. mushrooms & fungi, roots & tubers, pulses and legumes), and nuts & seeds	Food		
05.0	Confectionery			Exception a
06.0	Cereals and cereal products, incl. flours & starches from roots & tubers, pulses & legumes, excluding bakery	Food		
07.0	Bakery wares	Food		
08.0	Meat and meat products, including poultry and game	Food		
09.0	Fish and fish products, including molluscs, crustaceans and echinoderms	Food		
10.0	Eggs and egg products	Food		
11.0	Sweeteners, including honey			Exception a
12.0	Salts, spices, soups, sauces, salads, protein products, etc.			Exception d
13.0	Foodstuffs intended for particular nutritional uses	Food		
14.1	Non-alcoholic ("soft") beverages, excl. dairy products		Beverages	
14.2	Alcoholic beverages, incl. alcohol-free and low-alcoholic counterparts			Exception c

Table II.2.2 Distribution of the 18 food categories listed in Commission Regulation (EC) No 1565/2000 (EC, 2000a) into the seven SCF food categories used for TAMDI calculation (SCF, 1995)

Food categories according to Commission Regulation (EC) No1565/2000		Distribution of the seven SCF food categories
15.0	Ready-to-eat savouries	Exception b
16.0	Composite foods (e.g. casseroles, meat pies, mincemeat) - foods that could not be placed in categories 01.0 - 15.0	Food

The mTAMDI values (see Table II.2.3) are presented for each of the 61 flavouring substances in the present flavouring group, for which Industry has provided use and use levels (EFFA, 2001a; EFFA, 2003c; EFFA, 2003s; EFFA, 2004ag; EFFA, 2007a; Flavour Industry, 2006a; Flavour Industry, 2010g; Flavour Industry, 2010n). The mTAMDI values are only given for the highest reported normal use levels.

Table II.2.3 Estimated intakes based on the mTAMDI approach

FL-no	EU Register name	mTAMDI (µg/person/day)	Structural class	Threshold of concern (µg/person/day)
02.132	Butane-1,3-diol	3900	Class I	1800
02.198	Octane-1,3-diol	3900	Class I	1800
05.149	Glutaraldehyde	1600	Class I	1800
07.169	1-Hydroxypropan-2-one	1600	Class I	1800
08.053	Malonic acid	3200	Class I	1800
08.082	Glutaric acid	3200	Class I	1800
08.090	2-Hydroxy-4-methylvaleric acid	3800	Class I	1800
08.103	Nonanedioic acid	3200	Class I	1800
08.113	Succinic acid, disodium salt		Class I	1800

ANNEX III: METABOLISM

III.1. Introduction

III.1.1. Equilibrium Between Aliphatic Lactones and Ring-opened Hydroxycarboxylic Acids: Effect of pH

In general, lactones are formed by acid-catalysed intramolecular cyclisation of hydroxycarboxylic acids. In an aqueous environment, a pH-dependent equilibrium is established between the open-chain hydroxycarboxylate anion and the lactone ring. In basic media, such as blood, the open-chain hydroxycarboxylate anion is favoured while in acidic media, such as gastric juice and urine, the lactone ring is favoured (see Figure III.1). Enzymes, such as lactonase, may catalyse the hydrolysis reaction, but for simple saturated lactones, the ring-opening reaction and reverse cyclisation are in equilibrium, mainly controlled by pH conditions. Both the aliphatic lactones and the ring-opened hydroxycarboxylic acids can be absorbed from the gastrointestinal tract. However, the simple lactones, with low molecular weight, being uncharged, may cross the cell membrane more easily than the acidic form, which penetrates the cells as a weak electrolyte (Guidotti and Ballotti, 1970).

Figure III.1. Equilibrium of gamma- and delta-lactone and hydroxycarboxylate anion

III.1.2. Hydrolysis of Aliphatic Lactones

Fifteen candidate substances [FL-no: 10.038, 10.039, 10.040, 10.045, 10.047, 10.048, 10.049, 10.052, 10.055, 10.058, 10.059, 10.063, 10.068, 10.168 and 10.170] are simple aliphatic lactones that are expected to readily undergo hydrolysis *in vivo*.

Information on the disposition of these substances is mainly derived from studies on a single supporting substance, butyro-1,4-lactone [FL-no: 10.006], which has been extensively studied due to the production of CNS depression, attributed to its hydrolysis product, gamma-hydroxybutyrate. No data on the candidate substances are available.

When 4-hydroxybutanoic acid gamma-lactone (butyro-1,4-lactone) is administered intravenously (Roth and Giarman, 1966), intraperitoneally (i.p.) or orally (Guidotti and Ballotti, 1970) to rats, the open-chain 4-hydroxybutanoate anion is detected in the blood and tissues and the sedative effect produced by 4-hydroxybutanoate was evidenced (Roth and Giarman, 1966; Guidotti and Ballotti, 1970). The half-life for the conversion of the lactone ring to the open-chain anion in the blood is less than one minute. The reaction is catalysed by gamma-lactonase, which shows greater activity in the plasma than in the liver or brain (Fishbein and Bessman, 1966).

Hydrolysis of various aliphatic lactones (1 mM), including those formed from tertiary alcohols, has been described after *in vitro* incubation in basic simulated intestinal fluid and rat liver homogenate, (Morgareidge, 1962a; Morgareidge, 1963a).

Table III.1. Hydrolysis of various aliphatic lactones

Substance	Test System	% Hydrolysis	Time (hr)	Reference
Gamma-Valerolactone	Simulated intestinal fluid	32	4	(Morgareidge, 1962a)
	Rat liver homogenate	93	1	(Morgareidge, 1963a)
Gamma-Nonalactone	Rat liver homogenate (pH= 7.5)	62-94	1	(Morgareidge, 1963a)
	Rat liver homogenate (pH=8)	81-88	1	(Morgareidge, 1963a)
Gamma-Undecalactone	Simulated intestinal fluid	58	1	(Morgareidge, 1962a)
	Rat liver homogenate (pH= 7.5)	26-40	4	(Morgareidge, 1963a)
	Rat liver homogenate (pH= 8)	45-70	1	(Morgareidge, 1963a)
Omega-6-Hexadecenlactone	Simulated intestinal fluid	92	0.25	(Morgareidge, 1962a)
	Simulated intestinal fluid	96	1	(Morgareidge, 1963a)
4,4-Dibutyl-gamma-butyrolactone	Simulated intestinal fluid	92	1	(Morgareidge, 1962a)

As shown in Table III.1, the rate and the extent of hydrolysis differ, depending on the lactone tested. The observation that gamma-lactones, sterically hindered gamma-lactones and omega-lactones are hydrolysed to the ring-opened form under these conditions supports the conclusion that the ring-opened hydroxycarboxylic acid anion exists in body fluids at basic pH. In acidic media, such as the gastric juice and the urine, the lactone form predominates.

Gamma-valerolactone and gamma-hexalactone have been detected in the urine of normal human adults (Zlatkis and Liebich, 1971).

III.1.3. Absorption of Aliphatic Lactones

Aliphatic lactones or the ring-opened hydroxycarboxylic acids are expected to be absorbed from the gastrointestinal tract. In rats, single oral doses >100 mg/kg bw/day of the supporting substance gamma-butyrolactone [FL-no: 10.006] were absorbed rapidly and completely from the intestinal tract (Arena and Fung, 1980; Guidotti and Ballotti, 1970; Lettieri and Fung, 1978). However, the lactone being an uncharged low molecular weight molecule may cross the cell membrane more easily than the ring-opened form, which penetrates the cells as a weak electrolyte (Guidotti and Ballotti, 1970).

In humans, paraoxonase (PON1), a serum enzyme belonging to the class of A-carboxyesterases (Aldridge, 1953), is known to rapidly hydrolyse a broad range of aliphatic lactone substrates including beta-, gamma-, delta- and omega-lactones, lactones fused to alicyclic rings such as 2-(2-hydroxycyclopent-4-enyl)ethanoic

1 acid gamma-lactone (Billecke et al., 2000). Activities of paraoxonase isoenzymes (Q & R) in human blood
2 exhibit a bimodal distribution that is accounted for by a Q/R (glutamine or arginine) polymorphism with Q-
3 type homozygotes showing a lower activity than QR heterozygotes or R homozygotes (Humbert et al.,
4 1993).

5 Incubation of 1 mM of human R-type PON1 with aliphatic lactones gamma-butyrolactone, gamma-
6 valerolactone, gamma-decanolactone and undecano-gamma-lactone resulted in hydrolysis rates of 9.1, 7.0,
7 19.0 and 13.0 $\mu\text{mol/min/ml}$ substrate, respectively (Billecke et al., 2000). Hydrolysis is slower for the
8 alicyclic fused-ring lactone, 2-(2-hydroxycyclopent-4-enyl)ethanoic acid gamma-lactone, with a hydrolysis
9 rate of less than 3 $\mu\text{mol/min/ml}$ substrate in the Q and R isoenzymes of PON1 (Billecke et al., 2000).

10 Based on these data, it is concluded that a wide variety of lactones readily hydrolyse in human blood serum
11 support either prior to absorption or upon entering systemic circulation.

12 **III.1.4. Metabolism of Lactones Formed From Linear and Branched-chain Aliphatic Hydroxy-** 13 **carboxylic Acids**

14 No literature data on the candidate substances are available; however, due to the simple structure of the
15 substances, information on their metabolic fate may be derived from text books.

16 Linear aliphatic hydroxycarboxylic acids are hydrolysed and rapidly oxidised *via* the fatty acid pathway.
17 Linear saturated 5-hydroxycarboxylic acids formed from delta-lactones are converted, *via* acetyl coenzyme
18 A (CoA), to hydroxythioesters, which then undergo beta-oxidation and cleavage to yield an acetyl CoA
19 fragment and a new beta-hydroxythioester reduced by two carbons. Even numbered-carbon acids continue to
20 be oxidised and cleaved to yield acetyl CoA while odd numbered-carbon acids yield acetyl CoA and
21 propionyl CoA. Acetyl CoA enters the citric acid cycle directly while propionyl CoA is transformed into
22 succinyl CoA, which then enters the citric acid cycle (Voet and Voet, 1990).

23 Linear saturated 4- or 6-hydroxycarboxylic acids formed from gamma- or epsilon-lactones participate in the
24 same pathway as linear saturated 5-hydroxycarboxylic acids; however, loss of an acetyl CoA fragment
25 produces an alpha-hydroxythioester, which undergoes oxidation and alpha-decarboxylation to yield a linear
26 carboxylic acid and eventually carbon dioxide (Voet and Voet, 1990). In rats and dogs, the supporting
27 substances, $^{14}\text{CO}_1$ -gamma-decalactone and $^{14}\text{CO}_1$ -gamma-dodecalactone, are metabolised in a manner similar
28 to $^{14}\text{CO}_1$ -lauric acid, with approximately 75 % of the labeled ^{14}CO being eliminated as carbon dioxide within
29 48 hours (Fassett, 1961).

30 The metabolic fate of the supporting substance butyro-1,4-lactone [FL-no: 10.006] has been extensively
31 studied in animals and humans. The majority of ^{14}C -labeled 4-hydroxybutanoate administered by intravenous
32 injection to rats was recovered as $^{14}\text{CO}_2$ within 2.5 hours (Roth and Giarman, 1965). Oxidation of gamma-
33 butyrolactone to succinate by alcohol dehydrogenase and succinic semialdehyde dehydrogenase occurs
34 primarily in the liver (Jakoby and Scott, 1959); succinate then participates in the citric acid cycle (Doherty
35 and Roth, 1978; Lee, 1977; Möhler et al., 1976; Walkenstein et al., 1964). However, this pathway accounts
36 for only a limited proportion of the metabolised compound. The main biotransformation route through which
37 gamma-butyrolactone is metabolised is beta-oxidation as indicated by the presence of (S)-3,4-
38 dihydroxybutyric acid, glycolic acid and 3-oxobutyric acid in the urine of human volunteers given orally 1.0
39 g gamma-butyrolactone [FL-no: 10.006] (Lee, 1977); other intermediates derived from beta-oxidation have
40 previously been detected in samples of human urine (Walkenstein et al., 1964).

41 If the lactone is formed from a linear hydroxycarboxylic acid containing unsaturation, cleavage of acetyl
42 CoA units will continue along the carbon chain until the position of unsaturation is reached. If the
43 unsaturation begins at an odd-numbered carbon, acetyl CoA fragmentation will eventually yield a 3-enoyl
44 CoA, which is converted to the *trans*- Δ_2 -enoyl CoA before entering the fatty acid pathway. If unsaturation

begins at an even-numbered carbon, acetyl CoA fragmentation yields a Δ_2 -enoyl CoA product, which is a substrate for further fatty acid oxidation. If the stereochemistry of the double bond is *cis*, hydration yields (R)-3-hydroxyacyl CoA, which is isomerised to (S)-3-hydroxyacyl CoA by 3-hydroxyacyl CoA epimerase prior to entering into normal fatty acid metabolism (Voet and Voet, 1990).

The principal metabolic pathways utilized for detoxication of branched-chain hydroxycarboxylic acids are influenced by the chain length and the position and size of alkyl substituents. Short-chain (< C₆) branched aliphatic hydroxycarboxylic acids may be excreted conjugated mainly with glucuronic acid, or undergo alpha- or beta-oxidation followed by cleavage and complete metabolism to CO₂ (Voet and Voet, 1990; Williams, 1959a) via the fatty acid pathway and the tricarboxylic acid cycle. Alternatively, as chain length, substitution and lipophilicity increase, the hydroxycarboxylic acid may undergo a combination of omega-, omega-1 and beta-oxidation to yield polar hydroxyacid, ketoacid and hydroxydiacid metabolites that may be excreted as the glucuronic acid or sulphate conjugates in the urine and, to a lesser extent, in the faeces. Methyl substituted carboxylic acids are, to some extent, omega-oxidised in animals to form diacids, which can be detected in the urine (Williams, 1959a).

Carboxylic acids with a methyl substituent located at an even-numbered carbon (e.g. 2-methylpentanoic acid or 4-methyldecanoic acid) are metabolised extensively in the fatty acid pathway to CO₂ via beta-oxidation and cleavage of the longer branched-chain. If the methyl group is located at an odd-numbered carbon such as the 3-position, beta-oxidation is inhibited and omega-oxidation predominates, primarily leading to polar, acidic metabolites capable of being excreted in the urine as such or as conjugates (Williams, 1959a). Larger alkyl substituents (> C₂) located at the alpha- or beta-position inhibit metabolism to CO₂ (Albro, 1975; Deisinger et al., 1994; Deuel, 1957) in which case there is either direct conjugation of the acid with glucuronic acid or omega-oxidation leading to diacid metabolites, which may be conjugated and excreted.

III.2. Absorption, Metabolism and Elimination of: Esters, Acetals, Aliphatic Primary Alcohols, Aldehydes, and Carboxylic Acids Containing Additional Oxygenated Functional Groups

III.2.1. Mono- and Di-esters

Thirty-two candidate substances are esters or diesters [FL-no: 09.333, 09.345 - 09.354, 09.360, 09.502, 09.558, 09.565, 09.580, 09.590, 09.601, 09.626, 09.629, 09.633, 09.634, 09.644, 09.683, 09.815, 09.824, 09.832, 09.833, 09.862, 09.874 09.916 and 09.951]. They are expected to undergo hydrolysis in humans to yield their corresponding alcohol (linear or branched-chain aliphatic alcohols) and acid components (i.e. alpha-, beta- or gamma-keto or hydroxy acids; or simple aliphatic acids, diacids or triacids), which would be further metabolised. The presence of a second oxygenated functional group has little if any effect on hydrolysis of these esters; therefore the discussion and conclusions presented in previous evaluations (FGE.01 and FGE.02) apply equally well to the candidate esters in the present evaluation.

Hydrolysis is catalysed by classes of enzymes recognised as carboxylesterases or esterases (Heymann, 1980), the most important of which are the B-esterases (Anders, 1989; Heymann, 1980). Acetyl esters are the preferred substrates of C-esterases (Heymann, 1980). In mammals, these enzymes occur in most tissues throughout the body (Anders, 1989; Heymann, 1980) but predominate in the hepatocytes (Heymann, 1980).

The majority of degradation products yielded from the candidate ester hydrolysis are endogenous in mammals and are known to be completely metabolised, through different reactions, depending on their chain length and degree of branching and functional groups. It is likely that multiple metabolic reactions will occur for some hydrolysis products. The most probable metabolic reactions are the following:

- Oxidation of alcohols to aldehydes and acids.
- Conjugation of alcohols and acids to glucuronides and sulphates.
- Beta-oxidation of carboxylic acids.
- Omega-oxidations of carboxylic acids.

However, the hydrolysis product of the candidate substance ethyl 2-acetylbutyrate [FL-no: 09.824], 2-acetyl butyric acid, has some structural similarities to valproic acid, which together with a number of its derivatives has been recognised to be teratogenic in rodents and in humans (Nau and Löschner, 1986; Samren et al., 1997; Kaneko et al., 1999). Although it can be predicted that 2-acetyl butyric acid is further metabolised through the above mentioned pathways of detoxication for carboxylic acids, the structural similarity with valproic acid does not allow to anticipate that ethyl 2-acetylbutyrate [FL-no: 09.824] is metabolised to innocuous products.

While no hydrolysis data have been provided for the esters of the present group of flavourings, information on some structurally related esters could be found.

In vitro incubation of the supporting substance methyl 2-oxo-3-methylvalerate [FL-no: 09.550], with a 2 % pancreatin solution (pH = 7.5), resulted in virtually complete hydrolysis (> 98 %) within 80 minutes (Leegwater and VanStraten, 1979). The supporting substance dibutyl sebacate [FL-no: 09.474] in 10 % acacia solution, was hydrolysed *in vitro* in a 10 % crude pancreatic lipase solution (Smith, 1953b).

The supporting substance ¹⁴C-tributyl acetylcitrate [FL-no: 09.511], administered to male Sprague-Dawley rats by gavage at a dose level of 70 mg/kg bw, was rapidly absorbed (t_{1/2} = 1 hour) and partially hydrolysed. More than 87 % of the administered radioactivity was eliminated within 24 hours after dosing. At least nine urinary metabolites (59 - 70 %) were detected. Five metabolites were positively identified as the partially hydrolysed mono-, di- and tri-alkylesters of citric acid. Three metabolites (25 - 26 %) were identified in the faeces; approximately 2 % of the administered dose was eliminated as ¹⁴CO₂ (Hiser et al., 1992).

III.2.2.Acetals

Six candidate substances [FL-no: 06.088, 06.090, 06.095, 06.097, 06.102 and 06.135] are acetals, which may undergo acid catalysed hydrolysis in the gastric environment to yield their component aldehydes and alcohols prior to absorption.

In vitro experiments using simulated gastric fluid revealed the rates of hydrolysis of acetals to be dependent on the structures of the aldehyde and alcohol moieties. Acetals derived from short (< C8) chain saturated aldehydes were hydrolysed almost instantly (Engel, 2003).

Hydroxycitronellal dimethyl acetal similar to the supporting substance hydroxycitronellal diethyl acetal was > 99 % hydrolysed *in vitro* to the terpenoid hydroxycitronellal and methanol in simulated gastric juice (pH about 2.1) after 1 hour and > 6 % hydrolysed in intestinal fluid (pH = 7.5) after 2 hours (Morgareidge, 1962b).

Once hydrolysed, the component alcohol, aldehydes and acids are expected to be completely metabolised, through the above mentioned common routes of biotransformations and excreted.

III.2.3.Alpha-hydroxy- and Alpha-keto-acids and Their Esters

One candidate substance [FL-no: 08.090] is an alpha-hydroxyacid. In addition alpha-keto- and alpha-hydroxyacids are formed by hydrolysis of candidate esters [FL- No: 09.333, 09.346, 09.353, 09.565, 09.580,

09.590, 09.601, 09.626, 09.644, 09.683, 09.815 and 09.874]. They would be expected to be metabolised like endogenous alpha-ketoacids formed from oxidative deamination of amino acids such as isoleucine, methionine and valine *in vivo*.

The supporting substance, 2-oxobutyric acid [FL-no: 08.066] (i.e. alpha-ketobutyric acid), is endogenous in humans as a product of methionine degradation and undergoes alpha-decarboxylation to yield propionyl CoA. Propionyl CoA ultimately enters the tricarboxylic acid cycle as succinyl CoA (Voet and Voet, 1990).

III.2.4. Beta-keto- and Beta-hydroxyacids and Their Esters

One candidate substance [FL-no: 08.053] is a beta-ketoacid. In addition eight candidate substances [FL-no: 09.346, 09.558, 09.629, 09.634, 09.824, 09.862, 09.874 and 09.916] are precursor of acetoacetic acid or its beta-hydroxy or aldehyde precursor. [FL-no: 09.346, 09.629, 09.862, 09.874 and 09.916] can be oxidised *in vivo* to acetoacetic acid. Acetoacetic acid is endogenous in humans and is formed from the condensation of two acetyl CoA units in the fatty acid pathway. It is released from the liver into the bloodstream and transported to peripheral tissues where it is converted to acetyl CoA and is completely metabolised. At elevated endogenous levels, beta-ketoacids may undergo non-enzymatic decarboxylation, which, for acetoacetic acid, yields acetone and CO₂ (Voet and Voet, 1990).

III.2.5. Gamma-keto- and Gamma-hydroxyacids and Their Esters

Gamma-hydroxy and gamma-keto acids are produced by hydrolysis of two candidate substances [FL-no: 09.832 and 09.833]. They are expected to be completely metabolised to CO₂ at low levels of exposure from use as flavouring substances. At elevated levels of exposure, the ketone function may be reduced to the corresponding secondary alcohol (Bosron and Li, 1980) and excreted as the glucuronic acid conjugate (Williams, 1959a).

Products of partial beta-oxidation or glucuronic acid conjugation have also been identified in the urine. When 1.0 g of the structurally related substance gamma-hydroxybutyrate [FL-no: 10.006] was administered to humans, it was excreted in the urine as S-3,4-dihydroxybutyrate, 3-oxobutyric acid and glycolate (Lee, 1977).

III.2.6. Aliphatic Di- and Tricarboxylic Acids and Their Esters

Among candidate substances the aliphatic di- and tri-carboxylic acids and their precursors [FL-no: 05.149, 08.053, 08.082, 08.103, 08.113, 09.345, 09.346, 09.347, 09.348, 09.349, 09.350, 09.351, 09.352, 09.353, 09.354, 09.558, 09.874 and 09.951] either occur endogenously in humans or are structurally related to endogenous substances. Succinic acid (from [FL-no: 09.345 and 09.347]), fumaric acid (from [FL-no: 09.350]), L-malic acid (from [FL-no: 09.346 and 09.874]), maleic acid (from [FL-no: 09.351]) and citric acid (from [FL-no: 09.349]), are components of the tricarboxylic acid cycle (Voet and Voet, 1990). Fumaric acid is present in the blood, brain, liver, muscle and kidney of normal rats (Marshall et al., 1949). Moreover, the following acids are present in the urine of normal adults, citric, tartaric, malic, aconitic, fumaric and adipic (Hanson, 1943; Osteux and Laturaze, 1954). Alpha-ketoglutaric acid is an intermediate metabolite of citric acid, fumaric acid and succinic acid, and is formed via alpha-oxidation (Krebs et al., 1938; Simola and Krusius, 1938).

Simple aliphatic di- and tricarboxylic acid candidate substances and component acids of the candidate esters are metabolised in the fatty acid beta-oxidation pathway or tricarboxylic acid cycle. When the supporting substance ¹⁴C-L-malic acid [FL-no: 08.017] was administered to male albino Wistar rats by gavage at a dose level of 2.5 mg/kg bw, 93 % of the radioactivity was recovered in expired air, urine and faeces (Dargel, 1966).

After the administration of the radioactive supporting substance adipic acid [FL-no: 08.026] to rats by stomach tube at a dose level of 200 - 300 mg/kg bw, the compound was extensively metabolised. Labelled products identified in the urine included glutamic acid, lactic acid, beta-ketoadipic acid and citric acid. The presence of the beta-oxidation metabolite, beta-ketoadipic acid, indicates that adipic acid participates in beta-oxidation in the fatty acid pathway (Rusoff et al., 1960).

The linear and branched-chain aliphatic primary alcohol components of candidate substances that are simple aliphatic di- and tricarboxylic acid esters would be oxidised in the presence of alcohol dehydrogenase to their corresponding aldehydes which, in turn, would be oxidised to their corresponding carboxylic acids (Bosron and Li, 1980; Feldman and Weiner, 1972; Levi and Hodgson, 1989). The resulting carboxylic acids would be metabolised in the fatty acid pathway and tricarboxylic acid cycle (Voet and Voet, 1990) or conjugated to glucuronides and sulphates and excreted. Branched-chain diols or keto alcohols may undergo oxidation to their corresponding aldehydes and carboxylic acid, which would be further metabolised or excreted, through the common routes of biotransformation of carboxylic acids.

III.2.7. Aliphatic Alkoxy- alcohol and Diols

Among candidate substances, one is an alkoxy-alcohol [FL-no: 02.242] and two are diols [FL-no: 02.132 and 02.198].

The metabolism and disposition of 2-butoxyethanol [FL-no: 02.242] were extensively studied, and details are reported below. However, it can be anticipated that the major metabolite is butoxyacetic acid, which is primarily responsible for the hemolysis of red blood cells and other toxic effects induced by 2-butoxyethanol.

1-Hydroxypropan-2-one [FL-no: 07.169] (acetol) is an endogenous metabolite of acetone which is also an endogenous substance formed from the degradation of body fat/fatty acids.

The metabolism in mammals of acetone, which at low concentrations, primarily occurs in the liver, is shown in Figure III.2. At low acetone concentrations in blood, i.e. in healthy humans not exposed to external sources, in amounts of approximately 4 - 12 mg per person corresponding to 0.7 to 2 mg/l blood (Ashley et al., 1994; Dick et al., 1988; Wang et al, 1994c), the major pathway is via the methylglyoxal route. At higher acetone concentrations in the blood, e.g. after acetone exposure, after fasting or in relation to certain diseases the propan-1,2-diol route is the dominating pathway. In the first step acetone is oxidized to 1-hydroxypropan-2-one via acetone monooxygenase (p-450 IIE1). 1-Hydroxypropan-2-one is oxidised to 2-oxopropanal via acetol monooxygenase (p-450 IIE1), or at higher acetone concentrations to propan-1,2-diol. 2-Oxopropanal is then oxidised to pyruvate leading to glucose formation (Morgott, 1993; WHO, 1998a; NAS/COT, 2005).

The diols are anticipated to be metabolised by the common route of alcohol biotransformation, i.e. direct conjugation or oxidation by alcohol-dehydrogenase to their corresponding aldehydes and carboxylic acid, which would be further metabolised or excreted.

3 III.3. Studies on Candidate Substances

4 2-Butoxyethan-1-ol [FL-no: 02.242]

5 Several experiments by the oral route of administration have been conducted, indicating that 2-butoxyethan-
6 1-ol is rapidly absorbed, metabolised and eliminated. Butoxyacetic acid is its major metabolite, metabolism
7 being mainly catalysed by hepatic alcohol dehydrogenase; most excretion is in the urine (Corley et al., 1994;
8 Ghanayem et al., 1987a; Ghanayem et al., 1987b; Ghanayem et al., 1987c; Medinsky et al., 1990).

9 The distribution and excretion of ^{14}C -butoxyethanol and its metabolites was evaluated using male F344 rats
10 (9 - 13 weeks old). A single 125 or 500 mg/kg dose of ^{14}C -butoxyethanol was administered to each animal
11 via gavage. Animals were killed 48 hours post-administration and tissues excised. At 48 hours,
12 approximately 18 % and 10 % of the administered dose was exhaled as $^{14}\text{CO}_2$ for the 125 and 500 mg/kg
13 doses, respectively; whereas only between 2 and 3 % was excreted in the faeces. The percentage of the 125
14 mg/kg dose excreted in the urine (70 %) was significantly greater than the percentage excreted after the 500
15 mg/kg dose (40 %). Butoxyacetic acid was the only urinary metabolite detected for the 125 mg/kg dose; the
16 glucuronide conjugates of butoxyethanol and butoxyacetic acid (23 %) were also detected in the urine of
17 animals dosed with the higher dose. A small portion (8 %) of the 500 mg/kg dose was excreted in the bile 8
18 hours after dosing. Compared to the 125 mg/kg dose group, tissue concentrations of ^{14}C -butoxyethanol 48

hours after administration were significantly greater in specific organs of rats that received the 500 mg/kg dose. In both dose groups the highest concentration of radioactivity was detected in the forestomach, followed by the liver, kidneys, spleen and the glandular stomach (Ghanayem et al., 1987c).

The metabolism and excretion of 2-butoxyethan-1-ol [FL-no: 02.242] were evaluated using both young (4 to 5 weeks old) and adult (9 to 13 weeks old) male F344 rats with the same experimental design described in Ghanayem *et al.* (1987c), except that ^{14}C -butoxyethanol was administered at a single oral dose (500 mg/kg). There was a significantly higher proportion of the administered dose eliminated as CO_2 in young rats as compared to older rats. Similarly, a significantly higher proportion of the administered dose was excreted in the urine of the young rats. The butoxyacetic acid/butoxyethanol-glucuronide + butoxyethanol-sulphate ratio was significantly greater in older rats (Ghanayem et al., 1987a), which are consistently more susceptible to the toxic action of 2-butoxyethan-1-ol. There was a strong correlation between the amount of butoxyacetic acid in the urine and 2-butoxyethanol-induced haematotoxicity. Moreover, metabolic activation via alcohol and aldehyde dehydrogenases is a prerequisite for the induction of toxic effects, since pre-treatment of rats with pyrazole (alcohol dehydrogenase inhibitor) or cyanamide (aldehyde dehydrogenase inhibitor) protected rats against 2-butoxyethanol-induced haematotoxicity and increased the urinary amount of butoxyethanol-conjugates (glucuronide and sulphate) (Ghanayem et al., 1987b).

2-Butoxyethan-1-ol [FL-no: 02.242] was administered to male F344/N rats (11 to 12 weeks old) at concentrations in drinking water of 290, 860 and 2590 ppm over a 24 hours period. Butoxyethanol was administered as 2-butoxy[$\text{U-}^{14}\text{C}$]ethanol, and exhaled air, urine and faeces were collected over a 72 hours period. Most ^{14}C was excreted either in the urine or exhaled as CO_2 : 50 - 60 % of the administered dose was eliminated in the urine as butoxyacetic acid and 8 to 10 % as CO_2 . Analysis of urine samples collected during the 12 - 24 hours after dosing indicated that the majority of the radioactivity was associated with butoxyacetic acid while 10 % of the administered dose was identified as glycol ether. Minor levels of glucuronide conjugate of butoxyethanol and unmetabolised butoxyethanol were also reported (Medinsky et al., 1990).

Non-oxidative metabolism of 2-butoxyethan-1-ol [FL-no: 02.242] via fatty acid conjugation was also investigated in the liver of F344 male rats following a single oral administration of 500 mg/kg [ethyl-1,2- ^{14}C] 2-butoxyethanol. Animals were killed two hours after treatment and samples prepared for analysis. It was demonstrated that 2-butoxyethan-1-ol is metabolised non-oxidatively via conjugation with long-chain fatty acids, and the formation of these esters appears to be catalysed by the enzymes involved in fatty acid conjugation of xenobiotic alcohols. However, the biological significance of 2-butoxyethan-1-ol conjugation with fatty acids remains unclear, although several such lipid conjugates were found to be toxic in laboratory animals and cell lines (Kaphalia et al., 1996).

The elimination kinetics of 2-butoxyethan-1-ol were studied in a once-through isolated perfused rat liver system in the presence and absence of ethanol. Dose-dependent Michaelis-Menten kinetics were observed in the elimination of 2-butoxyethan-1-ol. The apparent K_m ranged from 0.32 to 0.70 mM and the maximum elimination rate ranged from 0.63 to 1.4 micromol/min/g liver in six experiments. The results support the hypothesis that 2-butoxyethan-1-ol is metabolised mainly via oxidation by alcohol dehydrogenase in the rat liver at concentration which can be considered representative of human exposure (Johanson et al., 1986).

Butane-1,3-diol [FL-no: 02.132]

Two groups of 14 rats were administered a control diet (70 % carbohydrate and 30 % fat) or a treatment diet (45 % carbohydrate, 30 % fat and 25 % butane-1,3-diol). Blood acetoacetate and beta-hydroxybutyrate concentrations were increased significantly and blood pyruvate concentration was decreased significantly in rats administered the treatment diet. Addition of butane-1,3-diol to *in vitro* liver tissue slices, as they were metabolising glucose to lactate and pyruvate, greatly decreased pyruvate levels and significantly increased lactate/pyruvate ratios. When butane-1,3-diol and glucose were used as substrates, there was a large increase in acetoacetate and beta-hydroxybutyrate formation in liver tissue slices with butane-1,3-diol. Therefore,

butane-1,3-diol is metabolised in the cytosol and converted by the liver *in vivo* and *in vitro* to ketones prior to its oxidation in the tricarboxylic acid cycle (Mehlman et al., 1971).

Tate *et al.* (1971) found that the conversion of butane-1,3-diol to beta-hydroxybutyrate in rat liver was strongly dependent in NAD⁺ and it was inhibited by pyrazole. Since pyrazole is a specific inhibitor of alcohol dehydrogenase (ADH), this inhibition indicated ADH as the catalyst in the catabolism in the cytosol of butane-1,3-diol to an intermediate, aldol. Aldol is then further oxidised to beta-hydroxybutyrate (Tate et al., 1971).

Diethyl maleate [FL-no: 09.351]

Traditionally diethyl maleate [FL-no: 09.351] has been utilised to acutely deplete reduced glutathione (GSH) in the tissues, since it forms GSH-conjugates very rapidly, causing a significant decrease in GSH content (Boyland & Chasseaud, 1970). The liver is the most sensitive organ to diethyl maleate-induced GSH depletion, generally occurring 30 - 90 minutes after intraperitoneal injection of the compound. In the rat, the formed GSH-conjugates are excreted in bile or as mercapturates in urine (Barnhart and Combes, 1978).

The excretion of mercapturic acid was determined in chimpanzees and rats after the administration of diethyl maleate [FL-no: 09.351]. The excretion rate of endogenous thioethers in the urine of untreated chimpanzees and rats was 18.0 and 94.4 micromol/kg bw/24 hours, respectively. The value in man was nearly the same as found in chimpanzees. The administration of diethyl maleate at 30, 75 and 200 mg/kg bw led to a dose-dependent increase in the excretion of urinary mercaptic acids in both species, but the increase in rats was about twice that of chimpanzees. Additional experiments indicate that the observed species differences are due to differences in the glutathione conjugation (Summer et al., 1979a).

Glutaric acid [FL-no: 08.082]

Rat liver mitochondria metabolise glutarate [FL-no: 08.082] at a slow rate as compared with glutaryl CoA. The stimulatory effect of citric acid cycle intermediates, NAD and CoA on glutarate metabolism was interpreted as a manifestation of their involvement in the activation of glutarate by a thiol transferase with succinyl CoA as the coenzyme A donor (Besrat et al., 1969).

Glutaraldehyde [FL-no: 05.149]

Material mass balance and pharmacokinetics studies were conducted with glutaraldehyde [FL-no: 05.149] in groups of F344 rats (four/sex) and New Zealand white rabbits (two/sex) using the intravenous route of exposure at dose volumes of 0.2 ml and 2.5 ml, respectively. Rats and rabbits received intravenous doses of 0.075 and 0.75 % glutaraldehyde in the tail vein or ear vein, respectively. Glutaraldehyde was distributed rapidly and eliminated when administered intravenously to rats and rabbits. When a single infusion of 0.075 % glutaraldehyde was administered, 75 to 80 % of the dose in the rat and 66 to 71 % in the rabbit were recovered as ¹⁴CO₂ during the first 24 hours following administration, with 80 % of the ¹⁴CO₂ being recovered during the first four hours. When a single infusion of 0.75 % glutaraldehyde was administered, the proportion of the dose recovered as ¹⁴CO₂ decreased and the amount of radioactivity recovered in urine, tissues and carcass increased as compared to the 0.075 % glutaraldehyde infusion. Also the average plasma concentration of radioactivity increased 10-fold in rats and rabbits with a 10-fold increase in dose, but the tissue concentration increased by an even greater amount. The results suggest that the mechanisms involved in the disposition of glutaraldehyde were saturated when the higher dose was administered and resulted in a shift in the elimination pathway (McKelvey et al., 1992). Although the metabolism of glutaraldehyde has not been studied in detail, it has been suggested that it is oxidised first to a mono- or dicarboxylic acid by aldehyde dehydrogenase (Weiner, 1980; Hjelle and Peterson, 1983) and then further oxidised through an acidic intermediate to CO₂ (McKelvey et al., 1992).

Nonanedioic acid [FL-no: 08.103]

Following intravenous administration in human volunteers, nonanedioic acid [FL-no: 08.103] and its major catabolite, pimelic acid, are found in serum and urine indicating transformation by mitochondrial beta-oxidative enzymes. Serum levels of nonanedioic acid are short-lived following a single 5 or 10 g intravenous (i.v.) infusion over 1-hour. In the first hour after the cessation of i.v. administration, serum levels of nonanedioic acid decreased to about 25 % of their peak values. Administration of multiple intravenous doses at the same concentrations as the one-hour doses produces sustained higher levels of nonanedioic acid in the serum during the period of administration (Passi et al., 1989).

III.4. Conclusions

In general, lactones are formed by acid-catalysed intramolecular cyclisation of hydroxycarboxylic acids. In an aqueous environment, a pH-dependent equilibrium is established between the open-chain hydroxycarboxylate anion and the lactone ring. In basic media, such as blood, the open-chain hydroxycarboxylate anion is favoured, while in acidic media, such as gastric juice and urine, the lactone ring is favoured.

Lactones formed from linear saturated and branched-chain aliphatic hydroxycarboxylic acids are hydrolysed to the corresponding hydroxycarboxylic acid that then enters the fatty acid pathway and undergoes alpha- or beta-oxidation and cleavage to form acetyl CoA and a chain-shortened carboxylic acid. The carboxylic acid is then reduced by two-carbon fragments until either acetyl CoA or propionyl CoA is produced. These fragments are then completely metabolised in the citric acid cycle.

Mono- and di-esters included in the present FGE are expected to undergo hydrolysis in humans to yield their corresponding alcohol (linear or branched-chain aliphatic alcohols) and acid components (i.e. alpha-, beta- or gamma-keto- or hydroxy-acids; or simple aliphatic acids, diacids or triacids), which would be further metabolised and excreted through the common pathways of detoxication of aliphatic alcohols and carboxylic acids). The hydrolysis product of the candidate substance ethyl 2-acetylbutyrate [FL-no: 09.824], 2-acetyl butyric acid, which shows some structural similarities to valproic acid, which together with a number of its derivatives, has been recognised to be teratogenic in rodents and in humans (Nau and Löscher, 1986; Samren et al., 1997; Kaneko et al., 1999). Therefore, it cannot be anticipated that ethyl 2-acetylbutyrate [FL-no: 09.824] is metabolised to innocuous products.

The presence of a second oxygenated functional group has little, if any, effect on hydrolysis of these esters. The most probable metabolic reactions of the hydrolysis products are: oxidation of alcohols to aldehydes and acids; conjugation of alcohols and acids to glucuronides and sulphates; beta-oxidation of carboxylic acids; omega-oxidations of carboxylic acids.

Beta-keto acids and derivatives like acetoacetic acid undergo decarboxylation. Along with alpha-keto and alpha-hydroxyacids, they yield breakdown products, which are incorporated into normal biochemical pathways. The gamma-keto-acids and related substances may undergo complete or partial beta-oxidation to yield metabolites that are eliminated in the urine. Omega-substituted derivatives are readily oxidised and/or excreted in the urine. Simple aliphatic di- and tricarboxylic acids participate in the tricarboxylic acid cycle.

Six candidate substances [FL-no: 06.088, 06.090, 06.095, 06.097, 06.102 and 06.135] are acetals, which may be expected to undergo acid catalysed hydrolysis in the gastric environment to yield their component aldehydes and alcohols prior to absorption. Once hydrolysed, the component alcohols and aldehydes are expected to be metabolised primarily through the above mentioned common routes of biotransformations and excreted.

The linear and branched-chain aliphatic primary alcohol components of candidate substances that are simple aliphatic di- and tricarboxylic acid esters would be oxidised in the presence of alcohol dehydrogenase to their

1 corresponding aldehydes which, in turn, would be oxidised to their corresponding carboxylic acids. The two
 2 diols [FL-no: 02.132 and 02.198] may be anticipated to participate in the same routes of biotransformation.

3 Among candidate substances, an alkoxy-alcohol 2-butoxyethanol [FL-no: 02.242] is mainly metabolised to
 4 butoxyacetic acid, which has been identified as the major responsible for the hemolysis of red blood cells
 5 and other toxic effects induced by 2-butoxyethanol.

6 In summary, it can be anticipated that primary and secondary aliphatic saturated or unsaturated alcohols,
 7 aldehydes, carboxylic acids, acetals and esters with an additional oxygenated functional group and aliphatic
 8 lactones included in the present FGE are generally hydrolysed and completely metabolised to innocuous
 9 products many of which are endogenous in humans, at the estimated level of intake as flavouring substances.

10 The consideration on the actual levels of intake becomes particularly relevant for one candidate substance,
 11 diethyl maleate [FL-no: 09.351]; as when administered at high doses, it is able to induce severe GSH
 12 depletion, due to its prompt metabolism to GSH-conjugates. This may also be the case for the structurally
 13 related diethyl fumarate [FL-no: 09.350].

14 For three of the candidate substances it cannot be concluded that they are metabolised to innocuous products.
 15 These are 2-butoxyethanol [FL-no: 02.242], the major metabolite of which butoxyacetic acid has been
 16 recognised as responsible for haematotoxic effects induced by 2-butoxyethanol [FL-no: 02.242], 1,1,3-
 17 triethoxypropane [FL-no: 06.097], which may be metabolised to the structurally related ethoxypropanoic
 18 acid and finally, ethyl 2-acetylbutyrate [FL-no: 09.824], whose hydrolysis gives rise to 2-acetylbutyric acid,
 19 with some structural similarities to valproic acid, a known teratogenic compound.

20

ANNEX IV: TOXICITY

Oral acute toxicity data are available for 16 candidate substances of the present Flavouring Group Evaluation from chemical groups 9, 13 and 30, for 43 supporting substances evaluated by the JECFA at the 49th and 53rd meetings (JECFA, 1998a; JECFA, 2000c). The supporting substances are listed in brackets.

M = Male; F = Female

NR: Not reported.

¹ Dosed in 5 % gum arabic.

² Data derived from a range-finding study.

³ Actual LD₅₀ not reported. Study conducted as a dose range-finder (DRF).

⁴ Actual LD₅₀ not reported. Value reported as approximate LD₅₀.

⁵ Data point not verified.

⁶ Actual LD₅₀ not reported. Value reported as MFD (assumed to be Median Fatal Dose).

⁷ Glutaraldehyde dosed as a 50 % (w/w) solution. The LD₅₀ is expressed as mg of actual active ingredients.

⁸ Test substance administered as a 25 % solution. The LD₅₀ is expressed as mg of actual active ingredients.

⁹ Test substance administered as a 45 % aqueous solution. The LD₅₀ is expressed as mg of actual active ingredients.

¹⁰ Dosed as a 6 % suspension in 0.5 % methyl cellulose.

¹¹ Actual LD₅₀ not reported. Value represents lowest dose level tested causing mortality. Animals dosed at 16,000 mg/kg had 100 % survival rate, while animals dosed at 32,000 mg/kg had 100 % fatality. Acute lethal dose for dibutyl sebacate is between 16,000 and 32,000 mg/kg.

¹² Value represents the maximum dose level tested. Animals dosed at 30,000 mg/kg had 100 % survival rate.

Subacute / Subchronic / Chronic / Carcinogenic toxicity data are available for five candidate substances of the present Flavouring Group Evaluation from chemical groups 9, 13 and 30 and for 20 supporting substances evaluated by the JECFA at the 49th and 53rd meetings (JECFA, 1998a; JECFA, 2000c). Furthermore, data are available for two structurally related substances. The supporting and structurally related substances are listed in brackets.

(Succinate, monosodium)	Rat; M,F 10/10	Drinking water	13 weeks	1250	(Maekawa et al., 1990) in (OECD, 2003)	
	Rat; M,F 50/50	Drinking water	2 years	2000	(Maekawa et al., 1990) in (OECD, 2003)	Monosodium succinate was given ad libitum in drinking water at levels of 0, 1, or 2 % to F344 rats (50 males, 50 females). No toxic lesion specifically caused by long-term administration of monosodium succinate was detected.
(Succinate, disodium hexahydrate)	Rat; M,F 12 /12	Gavage 0, 100,300, 1000 mg/kg)	Males: 52 days, starting at 14 days before mating. Females: Day 14 before mating until day 4 of lactation	Males: 100 Females: 300	MHLW, Japan 2002 in (OECD, 2003)	Combined repeated dose toxicity study with the reproduction/developmental toxicity screening test, guideline [OECD TG 422]. Euqivalent NOAEL for sodium succinate: males 60 mg/kg; females, 180 mg/kg.

NR: Not reported.

M = Male; F = Female.

a) Study summarised by JECFA at the 49th or 53rd meetings (JECFA, 1998a; JECFA, 2000c).

¹ Number of groups represents the number of treatment groups investigated. Control groups are not reported.

² This study was performed at either a single dose level or multiple dose levels that produced no adverse effects.

³ Article published in Russian. Data point not verified.

⁴ Six animals per treatment group. The treatment groups for males were not the same as the females. Males were administered 2000 or 6000 ppm of the test substance, while the corresponding dose levels for the females were 1600 and 4800 ppm, respectively.

⁵ Compared to the control group absolute and relative thymus weights were significantly lower in males. These findings were not seen in females receiving up to 650 mg/kg/day.

⁶ Animals dosed 5 days a week for five weeks.

⁷ Changes in absolute or relative testis weights were not observed.

⁸ A decrease in red cell count was noted in the 500 mg/kg dose group and higher dose groups.

⁹ No treatment related effects were noted upon mortality, ophthalmology or body weights in the males. Microscopic evaluation noted that the transitional cell carcinomas were found in the urinary bladder. The findings were indicated to be dose related.

¹⁰ Administered as the sodium salt.

¹¹ Rats fed a maximum dose of ca. 2500 mg/kg/day over a two-year period showed no gross or microscopic changes to their organs. There was no change in the incidence of tumours and mortality was unaffected. There was a slight reduction in body weight in animals dosed at ca. 1500 mg/kg/day and above.

¹² Animals were dosed for 19 gestational days prior to the three month exposure period that is reported.

¹³ The value of the study is limited by high mortality in all treatment and control groups.

Developmental and reproductive toxicity data are available for five candidate substances of the present Flavouring Group Evaluation from groups 9, 13 and 30 of the present Flavouring Group Evaluation and for two supporting substance evaluated by JECFA at the 49th and 53rd meetings (JECFA, 1998a; JECFA, 2000c). Furthermore, data are available for one structurally related substance. The supporting and structurally related substances are listed in brackets.

Chemical Name [FL-no:]	Species; Sex	Route	No. groups/ No. per group ¹	Duration (days)	NOAEL (mg/kg/day)	Reference	Comments
(Adipic acid [08.026])	Rabbit; F	Gavage	3/15	Developmental toxicity: Gestation days 7 – 19	Maternal: 15; Fetal: 15	(Hellwig, 1991b)	
	Rat; F	Gavage	4/24-28	Developmental toxicity: Gestation days 6 – 15	288	(Morgareidge, 1973d)	
	Mouse; F	Gavage	4/20 – 21	Developmental toxicity: Gestation days 6 – 15	263	(Morgareidge, 1973d)	
	Rabbit; F	Gavage	4/10 – 14	Developmental toxicity: Gestation days 6 – 18	250	(Morgareidge, 1974a)	
Nonanedioic acid [08.103]	Rat; F	Diet	1/20	Developmental toxicity: Gestation days 0 - 19	140	(Mingrone et al., 1983)	
	Rabbit; F	Diet	1/30	Developmental toxicity: Gestation days 0 - 19	200	(Mingrone et al., 1983)	
(Succinate, disodium hexahydrate)	Rat; M,F	Gavage (0, 100,300, 1000 mg/kg)	4 per sex/ 12	Males: 52 days, starting at 14 days before mating. Females: Day 14 before mating until day 4 of lactation	M, F: 1000	MHLW, Japan 2002 in (OECD, 2003)	Combined repeated dose toxicity study with the reproduction/developmental toxicity screening test, guideline [OECD TG 422]. Euqivalent NOAEL for sodium succinate: m, 600 mg/kg.

M = Male; F = Female.

NR = Not Reported.

FACB = Fertility Assessment by Continuous Breeding.

¹ Number of groups represents the number of treatment groups investigated. Control groups are not reported.

² Dose range-finding phase: Based on the results of this dose range-finding study the highest concentration investigated further was 2 % in the drinking water.

³ Mice were exposed to the test article for a seven day premating period, followed by a 14 week cohabitation/breeding period.

⁴ Continuous breeding phase: All breeding pairs in the 0.5 % treatment group were fertile (delivered at least one litter). The fertility of the 1.0 and 2.0 % treatment groups was significantly affected.

⁵ Crossover mating trial: Reproductive capacity of female mice is relatively more susceptible than males under the same exposure conditions.

⁶ Offspring reproductive performance phase: Reproductive performance was not affected, but the mean liver and kidney weights for females was significantly different from that of the control group when organ weight was adjusted for body weight.

⁷ 1180 mg/kg/day was the only dose level tested. Compared to the control group the 1180 mg/kg/day decreased the number of viable litters; therefore increasing the number of failed pregnancies. There were no significant observations noted in the liveborn pups.

⁸ Dose related reproductive effects were noted after five successive matings of the F1A generation.

⁹ F₀ and F₁ animals dosed for a 10 week pre-breeding period and through mating, and gestation and lactation of offspring.

¹⁰ Glutaraldehyde was evidentially unpalatable, as water consumption was reduced in the mid- and high-dose groups; however, no signs of toxicity were observed at these dose groups.

In vitro mutagenicity/genotoxicity data are available for nine candidate substances of the present Flavouring Group Evaluation from chemical groups 9, 13 and 30 of the present Flavouring Group Evaluation and for 22 supporting substance evaluated by JECFA at the 49th and 53rd meetings (JECFA, 1998a; JECFA, 2000c). Furthermore, data are available for one structurally related substance. Supporting and structurally related substances are listed in brackets.

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
(Butyro-1,4-lactone [10.006])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535	0.1 - 50 µmoles/plate (8.6 - 4305 µg/plate)	Negative ¹	(Loquet et al., 1981)	No control values are given for inactive compounds. Conclusion not comprehensible.
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA102	0.013 - 1.3 mmol (11.2 - 1120 µg/ml)	Negative ¹	(Aeschbacher et al., 1989)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537	100 - 10000 µg/plate	Negative ¹	(NTP, 1992e)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1537	5,000 or 2000 µg/plate	Negative ¹	(MacDonald, 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537	0 - 10000 µg/plate	Negative ¹	(Haworth et al., 1983)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537	NR	Negative ¹	(Garner et al., 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	4 - 2500 µg/plate	Negative ¹	(Trueman, 1981)	
	Ames test	<i>S. typhimurium</i> TA92, TA98, TA100, TA1535, TA1537, TA1538	0.2 - 2000 µg/plate	Negative ¹	(Brooks and Dean, 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	10000 µg/ml	Negative ¹	(Baker and Bonin, 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	500 µg/plate	Negative ¹	(Rowland and Severn, 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	500 µg/plate	Negative ¹	(Simmon and Shephard, 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1537	NR	Negative ¹	(Nagao and Takahashi, 1981)	
	Ames test	<i>S. typhimurium</i> TA98, TA100	1000 mg	Negative ¹	(Ichinotsubo et al., 1981b)	
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	10 - 10000 µg/plate	Negative ³	(Richold and Jones, 1981)	
	Reverse bacterial mutation assay	<i>E. coli</i> WP2 (p)	up to 500 µg/plate (high dose studies) up to 100 µg/plate (low dose studies)	Negative ³	(Venitt and Crofton-Sleigh, 1981)	
	Reverse bacterial mutation assay	<i>E. coli</i> SA500	NR	Lethal ⁴	(Dambly et al., 1981)	
	Reverse mutation assay	<i>E. coli</i> WP2 <i>uvrA</i> pKM102	NR	Negative ¹	(Matsushima et al., 1981)	
	Forward mutation assay	<i>S. typhimurium</i> TM677	1000 µg/ml	Negative ³	(Skopect et al., 1981)	
	Microtiter fluctuation test	<i>S. typhimurium</i> TA98, TA1535, TA1537	10 - 1000 µg/ml	Negative ³	(Gatehouse, 1981)	
	Microtiter fluctuation test	<i>S. typhimurium</i> TA98, TA100	NR	Negative ³	(Hubbard et al., 1981)	
(Butyro-1,4-lactone [10.006]) continued	Microtiter fluctuation test	<i>E. coli</i> WP2 <i>uvrA</i>	10 - 1000 µg/ml	Negative ³	(Gatehouse, 1981)	Reliable study, conclusion comprehensible.
	Rec-assay	<i>Bacillus subtilis</i> H17, M45	20 µl (20000 µg)	Positive ¹	(Kada, 1981)	
	Differential killing test	<i>E. coli</i> WP2 <i>pol A</i> , WP2 <i>uvrA</i> , WP67 <i>uvrA</i> , WP67 <i>pol A</i> , CM871 <i>uvrA recA</i> , <i>LexA</i>	NR	Negative ¹	(Green, 1981)	

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
	Differential killing test	<i>E. coli</i> WP2 <i>pol A</i> , WP2 <i>uvrA</i> , WP67 <i>uvrA</i> , WP67 <i>pol A</i> , CM871 <i>uvrA recA</i> , <i>LexA</i>	1000 µg/ml	Negative ²	(Tweats, 1981)	
	Mitotic crossing-over	<i>S. cerevisiae</i>	1000 µg/ml	Negative ¹	(Kassinova et al., 1981)	
	Mitotic gene conversion	<i>S. cerevisiae</i> (JDI)	750 µg/ml	Negative ²	(Sharp and Parry, 1981)	
	Cell growth inhibition	<i>S. cerevisiae</i> (JDI)	750 µg/ml	Negative ²	(Sharp and Parry, 1981)	
	DNA polymerase I inhibition test	<i>E. coli</i> W3110 & P3478	10 µl (10000 µg)	Positive ² Negative ³	(Rosenkranz et al., 1981)	Reliable study, conclusion comprehensible.
	Forward mutation assay	<i>S. Pombe</i>	20 µg/ml ¹	Negative ³	(Loprieno, 1981)	
	Unscheduled DNA synthesis	Human HeLa S3 cells	0.1 - 100 µg/ml	Negative ¹	(Martin and McDermid, 1981)	
	ADP-ribosyl transferase activity	Human FL cells	10 ⁻³ to 10 ⁻⁷ mol/L (0.0086 – 86 µg/ml) ³	Negative	(Yingnian et al., 1990)	
	Clastogenic activity	Rat liver cell line RL1	250 µg/ml	Negative	(Dean, 1981)	
	Mammalian cell transformation	BHK-21 hamster kidney cells	250 µg/ml	Positive ¹	(Styles, 1981)	No specific genotoxicity endpoint.
	Degranulation assay	Rat	25 mg/ml (25000 µg/ml)	Positive	(Fey et al., 1981)	No genetic endpoint (displacement of polysomes from ER).
	Sister chromatid exchange	Chinese hamster ovary cells	494 - 4940 µg/ml 494 - 1480 µg/ml 3010 - 4940 µg/ml	Negative ² Negative ³ Positive ³	(NTP, 1992e)	Study in compliance with NTP laboratory health and safety requirements, conclusion comprehensible.
	Chromosomal aberration	Chinese hamster ovary cells	400 - 2580 µg/ml 400 - 1500 µg/ml > 2580 µg/ml	Negative ² Negative ³ Positive ³	(NTP, 1992e)	Study in compliance with NTP laboratory health and safety requirements, conclusion comprehensible. Cells were selected for scoring on the basis of good morphology and completeness of karyotype.
Pentano-1,5-lactone [10.055]	Microbial assay	<i>E. coli</i> B/rWP2(<i>trp</i> ⁻), WP2(<i>trp</i> ⁻), WP2(<i>uvrA</i> ⁻)	1 - 3 mg/plate (1000-3000 µg/plate)	Negative ⁵	(Kuroda et al., 1986)	Review, data cannot be validated.
(Hexano-1,5-lactone [10.010])	Ames test	<i>S. typhimurium</i> TA98, TA100	NR	Negative ²	(Kawachi et al., 1980b)	Summary of results on 186 compounds. No details on methods, concentrations and data given, results cannot be validated.
	Rec-assay	<i>B. subtilis</i>	NR	Negative ²	(Kawachi et al., 1980b)	Summary of results on 186 compounds. No details on methods, concentrations and data given, results cannot be validated.
	Sister chromatid exchange	Hamster lung fibroblast cells	NR	Negative ³	(Kawachi et al., 1980b)	Summary of results on 186 compounds. No details on methods, concentrations and data given, results cannot be validated.
	Chromosomal aberration	Hamster lung fibroblast cells	NR	Positive ²	(Kawachi et al., 1980b)	Summary of results on 186 compounds. No details on methods, concentrations and data given, results cannot be validated.
	Chromosomal aberration	Human embryo fibroblast cells	NR	Negative ³	(Kawachi et al., 1980b)	Summary of results on 186 compounds. No details on methods, concentrations and data given, results cannot be validated.
(Heptano-1,4-lactone [10.020])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	100,000 µg/plate	Negative ¹	(Heck et al., 1989)	Abstract only, study cannot be validated.
	Unscheduled DNA synthesis	Rat hepatocytes	3000 µg	Negative ¹	(Heck et al., 1989)	Abstract only, study cannot be validated.
(Nonano-1,4-lactone [10.001])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	37500 µg/plate	Negative ¹	(Heck et al., 1989)	Abstract only, study cannot be validated.
	Mammalian	Mouse lymphoma L5178y TK ^{+/+}	1000 µg/ml	Negative ²	(Heck et al., 1989)	Abstract only, study cannot be validated.

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
(Undecano-1,4-lactone [10.002])	Unscheduled DNA synthesis	Rat hepatocytes	600 µg/ml	Positive ³	(Heck et al., 1989)	Abstract only, study cannot be validated.
	Mutation assay	<i>E.coli</i> WP2 <i>uvrA</i>	500 µg	Negative ¹	(Yoo, 1986)	Methods in Japanese, tables only in English. Study cannot be validated
	Rec-assay	<i>B. subtilis</i> M45 & H17	0.2 - 1.6 mg/plate (200-1600 µg/plate)	Negative ⁴	(Yoo, 1986)	Methods in Japanese, tables only in English. Study cannot be validated
	Ames test	<i>S. typhimurium</i> TA92, TA94, TA98, TA100, TA1535, TA1537, TA2637	20 µl/disk (20000 µg/disk)	Positive ⁴	(Yoo, 1986)	Methods in Japanese, tables only in English. Study cannot be validated
	Ames test	<i>S. typhimurium</i> TA97, TA98, TA100, TA102	5 mg/plate (5000 µg/plate)	Negative ¹	(Ishidate et al., 1984)	
	Rec-assay	<i>B. subtilis</i> H17 & M45	0.1 mg/disk (100 µg/disk)	Negative ¹	(Fujita and Sasaki, 1987)	
	Rec-assay	<i>B. subtilis</i> H17 & M45	19 µg	Negative ¹	(Oda et al., 1979)	
(Undecano-1,5-lactone [10.011])	Rec-assay	<i>B. subtilis</i> H17 & M45	10 µl/plate (10000 µg/plate)	Positive ⁶	(Yoo, 1986)	Methods in Japanese, tables only in English. Study cannot be validated.
	Rec-assay	<i>B. subtilis</i> H17 & M45	10 µl/plate (10000 µg/plate)	Positive ³	(Kuroda et al., 1984a)	Abstract only translated, study cannot be validated.
	Chromosomal aberration	Chinese hamster fibroblast	0.5 mg/ml (500 µg/ml)	Negative ¹	(Ishidate et al., 1984)	
	Rec-assay	<i>B. subtilis</i> H17 & M45	19 µg	Negative ¹	(Oda et al., 1979)	
	Rec-assay	<i>B. subtilis</i>	10 µl/plate (10000 µg/plate)	Positive ¹	(Kuroda et al., 1984a)	Abstract only translated, study cannot be validated.
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA102	50 µmol (12 µg/ml)	Negative ¹	(Aeschbacher et al., 1989)	
	Ames test	<i>S. typhimurium</i> TA98, TA100	5 - 50 µg/plate	Negative ¹	(Turek et al., 1997)	
(Dodec-6-eno-1,4-lactone [10.009])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537	500 µg/plate	Negative ¹	(Watanabe and Morimoto, 1990)	
	Rec-assay	<i>E. coli</i> WP2 <i>uvrA</i>	500 µg/plate	Negative ¹	(Watanabe and Morimoto, 1990)	
1-Hydroxypropan-2-one [07.169]	Ames test	<i>S. typhimurium</i> TA100	20 - 400 µg/plate	Positive ¹	(Yamaguchi, 1982)	Effect dose-dependent, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA104	68 µmoles (5 µg/ml)	Positive ²	(Marnett et al., 1985a)	Authors state that each compound was tested to its toxic limits, data for maximum non-toxic dose given only.
	Ames test	<i>S. typhimurium</i> TA100	500 µg/plate	Positive ¹	(Yamaguchi and Nakagawa, 1983)	Numerical value given was obtained from dose-response curves of five concentration levels.
	Ames test	<i>S. typhimurium</i> TA100	NR	Positive ²	(Garst et al., 1983)	Appropriate controls (idomethan for volatile compounds, sterility of compounds and solvent). Test compound judged positive when dose-related doubling of revertants were found.
(Ethyl 3-hydroxybutyrate [09.522])	Ames test	<i>S. typhimurium</i> TA97, TA98, TA100, TA1535	NR	Negative ⁴	(Zeiger and Margolin, 2000)	
(Ethyl acetoacetate [09.402])	Ames test; preincubation protocol	<i>S. typhimurium</i> TA92, TA100, TA1535, TA1537, TA94 and TA98	25 mg/plate (25000 µg/plate)	Negative ¹	(Ishidate et al., 1984)	
	Ames test; preincubation protocol	<i>S. typhimurium</i> TA97, TA102	0.1 - 10 mg/plate (10 - 10000 µg/plate)	Negative ¹	(Fujita and Sasaki, 1987)	
	Rec-assay	<i>B. subtilis</i> ; H17, M45	20 µg/disk	Negative ¹	(Oda et al., 1979)	
	Rec-assay	<i>B. subtilis</i> ; H17, M45	20 µl/disk (20000 µg/disk)	Positive	(Yoo, 1986)	Methods in Japanese, tables only in English. Study cannot be validated.
	Rec-assay	<i>E. coli</i> ; WP2 <i>uvrA</i>	200 - 1600 µg/plate	Positive ⁸	(Yoo, 1986)	Methods in Japanese, tables only in

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
Methyl acetoacetate [09.634]	Rec-assay	<i>B. subtilis</i> ; H17, M45	10 - 20 µl/ml (10 - 20 µg/ml)	Negative ¹	(Kuroda et al., 1984a)	English. Study cannot be validated.
	Rec-assay	<i>B. subtilis</i> ; H17, M45	10 - 20 µl/ml (10 - 20 µg/ml)	Positive ¹	(Kuroda et al., 1984a)	Abstract only translated. Study cannot be validated.
	Chromosomal aberration	Chinese hamster fibroblast cells	1 mg/ml (2000 µg/ml)	Negative ¹	(Ishidate et al., 1984)	Abstract only translated. Study cannot be validated.
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538 <i>E. coli</i> WP2 <i>uvrA</i>	1 - 5000 µg/plate	Negative ¹	(Shimizu et al., 1985)	Modified Ames, reincubation. Reliable study, conclusion comprehensible.
2-Butoxyethan-1-ol [02.242]	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	10 - 5000 µg/plate	Negative ¹	(Okamoto and Riccio, 1985)	Study performed in compliance with US-FDA GLP standards. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537 <i>E. coli</i> WP2 <i>uvrA</i>	9.8 - 156.3 µg/plate	Negative ¹	(Henrich and McMahon, 1988)	Test material: mixture of 2-butoxyethanol (2 % w/v) with trichlorobenzene and anionic emulsifiers. Test compound produced no revertants vs solvent control.
	Ames test	<i>S. typhimurium</i> TA97, TA98, TA100, TA102, TA104, TA1535, TA1537	100 - 10000 µg/plate	Negative ¹	(Zeiger et al., 1992)	NTP-study within mutagenicity testing program. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA97, TA98, TA100, TA1535, TA1537, TA1538	5000 - 20000 µg/plate	Negative ¹	(Sippel, 1977)	Negative as defined by less than 2-times of the spontaneous reversion rate. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA97a, TA100 <i>E. coli</i> WP2 <i>uvrA</i>	500 - 1000 µg/plate	Negative ¹	(Gollapudi et al., 1996)	Re-examination of EGBE to valdazte report by Hoflack et al (1995) on mutagenicity of the compound in a test with TA97a. reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA97a, TA98, TA100, TA102	14 mg/plate (14000 µg/plate) conc. range: 0.8 - 115 micromol/plate, positive ab 19 micromol = 2,2mg/plate	Negative with TA98, TA100,TA102, positive with TA97a ¹	(Hoflack et al., 1995)	Positive with TA97a, but not reproduced in study specifically addressing this finding (Gollapudi et al., 1996).
	Mutagenicity Assay	Bacteriophage <i>T4D</i> <i>E. coli</i> <i>CR63</i> and <i>K12</i>	19.6 - 111.1 µl/ml	Negative ⁹	(Kvelland, 1988)	Highly toxic at all concentrations tested, bacteriophage yield less than 1 %.
	Forward mutation assay	Chinese hamster ovary cells V79	16.92 mM (2000 µg/ml) ³	Positive ²	(Elias et al., 1996)	It is noted that doses applied exceeded the maximum recommended doses according to current OECD guidelines.
	Forward mutation assay	Chinese hamster ovary cells V79	1 %	Negative ¹	(Slesinski and Weil, 1980)	Reliable study (5 concentrations each test, 1 % without S9 (non-toxic), 0.3 % with S9), conclusion comprehensible.
	Forward mutation assay	Chinese hamster ovary cells AS52	0.38 - 7.6 mM (898 µg/ml)	Negative ¹	(Chiewchanwit and Au, 1995)	Non-cytotoxic concentration range. Reliable study, conclusion comprehensible.
	Sister chromatid exchange	Chinese hamster ovary cells	0.007 - 0.25 %	Negative ¹	(Slesinski and Weil, 1980)	Reliable study, conclusion comprehensible.
	Sister chromatid exchange	Chinese hamster ovary cells V79	16.92 mM (2000 µg/ml)	Positive ^{2, 10}	(Elias et al., 1996)	It is noted that doses applied exceeded the maximum recommended doses according to current OECD Guidelines.
	Sister chromatid exchange	Human peripheral lymphocytes	3000 ppm	Positive ¹	(Villalobos-Pietrini et al., 1989)	Cited in review on 2-Butoxyethanol. Study cannot be evaluated.
	Sister chromatid exchange	Chinese hamster ovary cells	5000 µg/ml	Negative ¹	(NTP, 2000b)	NTP-study within mutagenicity testing

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
2-Butoxyethan-1-ol [02.242] continued	Chromosomal aberrations	Chinese hamster ovary cells	5000 µg/ml	Negative ¹	(NTP, 2000b)	program. Reliable study, conclusion comprehensible.
	Chromosomal aberrations	Chinese hamster ovary cells V79	16.92 mM (2000 µg/ml)	Negative ²	(Elias et al., 1996)	NTP-study within mutagenicity testing programme. Reliable study, conclusion comprehensible.
	Chromosomal aberrations	Human peripheral lymphocytes	3000 ppm	Negative ²	(Villalobos-Pietrini et al., 1989)	Reliable report with details on purity of test compounds, methods and results. 50 % growth inhibition (at 24 hours) approx. at 90 mM, but value cannot be precisely derived from the graphic presentation.
	Chromosomal aberrations	Human lymphocytes	16.92 mM (2000 µg/ml)	Negative ²	(Elias et al., 1996)	Cited in review on 2-Butoxyethanol. Study cannot be evaluated.
	<i>In vitro</i> micronucleus test	V79 cells	16.92 mM (2000 µg/ml)	Positive ²	(Elias et al., 1996)	No information on growth inhibition/survival of treated human lymphocytes given.
	Unscheduled DNA synthesis	Rat hepatocytes	0.1 - 100 x 10 ⁻³ %	Positive ^{1,11}	(Slesinski and Weil, 1980)	It is noted that doses applied exceeded the maximum recommended doses according to current OECD Guidelines.
	Embryo Transformation Assay	Syrian hamster embryo cells	NR	Negative ²	(Elias et al., 1996)	The interpretation of these findings is equivocal due to the methodology applied (liquid scintillation) and the absence of relation with dose.
(3,7-Dimethyloctane-1,7-diol [02.047])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	3.6 mg/plate (3600 µg/plate)	Negative ¹	(Brauninger, 1995)	No specific genotoxic endpoint.
(3,7-Dimethyl-7-hydroxyoctanal [05.012])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	3.6 mg/plate (3600 µg/plate)	Positive ⁴	(Wild et al., 1983)	
(1,1-Dimethoxy-3,7-dimethyloctan-7-ol [06.011])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537, TA1538	3.6 mg/plate (3600 µg/plate)	Negative ¹	(Wild et al., 1983)	
(Diethyl malonate [09.490])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537	3 µmol/plate (480 µg/plate)	Negative ¹	(Florin et al., 1980)	
(Dimethyl succinate [09.445])	Ames test	<i>S. typhimurium</i> TA98, TA100, TA1535, TA1537	20000 µg/plate	Negative ¹	(Andersen and Jensen, 1984a)	
	Ames test	<i>S. typhimurium</i> TA97, TA98, TA100, TA102, TA104, TA1535, TA1537, TA1538	10 mg/plate (10000 µg/plate)	Negative ¹	(Zeiger et al., 1992)	
(Fumaric acid [08.025])	Ames test	<i>S. typhimurium</i> TA100	1000 µg/plate	Negative ⁴	(Rapson et al., 1980)	
	Ames test (preincubation)	<i>S. typhimurium</i> TA97, TA98, TA100, TA1535, TA1537	2000 µg/plate	Negative ¹	(Zeiger et al., 1988)	
	Ames test	<i>S. typhimurium</i> TA92, TA94, TA98, TA100, TA1535, TA1537	10 mg/plate (10000 µg/plate)	Negative	(Ishidate et al., 1984)	
	Chromosomal aberrations	Chinese Hamster fibroblast cells	0.5 mg/ml (500 µg/ml)	Negative	(Ishidate et al., 1984)	
(l-Malic acid [08.017])	Ames test	<i>S. typhimurium</i> TA97, TA98, TA100, TA104	2000 µg/plate	Negative ¹	(Al-Ani and Al-Lami, 1988)	

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
Diethyl maleate [09.351]	Forward mutation assay	Mouse lymphocytes L5178Y TK+/-	2.250 - 9.750 x 10 ⁻⁴ mol/l (387 - 1679 µg/ml)	Positive ¹	(Wangenheim and Bolcsfoldi, 1988)	No S9 at 2.25 - 9.75 x 10 ⁻⁴ mol/L, doubling of the mutation rate at 6 x 10 ⁻⁴ mol/L and above, but growth reduction of 70 % or more. Study of insufficient value.
	Aneuploidy test	Chinese hamster lung cells V79	5.2 x 10 ⁻⁶ M 8.7 x 10 ⁻⁶ M	Negative ⁴ Positive ⁴	(Önfelt, 1987)	Reliable study, conclusion comprehensible.
Glutaric acid [08.082]	REC assay Ames	<i>B subtilis</i> M45 & H17 <i>S. typhimurium</i> TA98, TA100	NR	Negative ¹	(Sakagami et al., 1989)	Abstract, data cannot be validated.
Glutaraldehyde [05.149]	Ames test	<i>S. typhimurium</i> TA104	0.5 µmoles (50.06 µg/ml)	Positive ²	(Marnett et al., 1985a)	TA104 tested to reassess mutagenic potency of 28 carbonyl compounds. Dose-dependent increase toxic limits of glutaraldehyde. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA1535, TA100, TA1537, TA98	10 mg/plate (10000 µg/plate)	Equivocal ¹² Positive ¹²	(Haworth et al., 1983)	Part of ring study for re-assessment of 250 chemicals. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA100, TA102, TA104	25 - 300 µg/plate	Positive ¹	(Dillon et al., 1998)	Comparative analysis of TA100, TA102 and TA104 for sensitivity to 13 aldehydes and 4 peroxides. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA102, TA2638, <i>E. coli</i> WP2/pKM101, WP2 <i>uvrA</i>	20 - 1000 µg/plate	Positive ^{3,*}	(Watanabe et al., 1998a)	*Cytotoxicity noted in doses as low as 250 µg/plate. Ring study (22 laboratories) for comparative analysis of TA102, TA2638, <i>E. coli</i> WP2/pKM101 and WP2 <i>uvrA</i> /pKM101. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA102, <i>E. coli</i> WP2/pKM101, WP2 <i>uvrA</i>	5 - 100 µg/plate	Positive ²	(Wilcox et al., 1990)	Comparative analysis of TA102 and <i>E. coli</i> WP2 strains. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA102	1000 µg/plate	Positive ¹³	(Müller et al., 1993)	Ring study (3 laboratories) to evaluate TA102. Reliable, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA102, TA2638a	76 µg/plate	Positive ^{3,14}	(Rydén et al., 2000)	Comparative analysis on the sensitivity of bacterial strains and the possibility of using TA2638a. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA102	25 µg/plate	Positive ¹	(Levin et al., 1982)	Test of TA102 for detection of oxidative mutagens. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA97a, TA98, TA100, TA102, TA104	0.1 - 60 µg/plate	Positive ¹	(Noblitt et al., 1992)	Abstract, data cannot be validated.
	Ames test	<i>S. typhimurium</i> TA1535, TA100, TA1537, TA98, <i>E. coli</i> WP2 <i>uvrA</i>	100 - 5000 µg/plate	Negative ¹	(Wagner, 1997)	Study in compliance with inter-national (US-FDA, US-EPA, UK, Japan) GLP Guidelines. Negative result not discussed in view of positive results in other studies. Reliable study, conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA1535, TA100,	15.4 µg/plate ^{2,15}	Negative ¹	(Slesinski et al., 1983)	Lack of mutagenic activity considered to be

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
Glutaraldehyde [05.149] continued		TA1537, TA1538, TA98	51.6 µg/plate ³			due to reaction of glutaraldehyde with proteins in cell membrane, cytosol.
	Ames test	<i>S. typhimurium</i> TA97a, TA98, TA100, A102, TA104	0.050 % in 100 µl/plate (100000 µg/plate)	Positive ¹⁴	(Schweikl et al., 1994)	Study aimed at elucidating the mutagenic potency of 3 different dentin bonding agents, pure glutaraldehyde was tested as one of the ingredients of these materials. Conclusion comprehensible.
	Ames test	<i>S. typhimurium</i> TA100, TA98	20 µg/plate	Negative ¹	(Sakagami et al., 1988)	Dose-dependent DNA-damage. At minimum inhibitory concentration Ames test less sensitive than REC-assay (see below).
	Ames test	<i>E. coli</i> WP2 <i>uvrA</i>	20 - 10000 µM (2 - 1001 µg/ml)	Negative ²	(Hemminki et al., 1980)	Study aimed at comparison of alkylation rate with mutagenicity of directly acting chemicals, glutaraldehyde served as reference compound.
	Rec-assay	<i>B. subtilis</i> , M-45 (<i>Rec</i> ⁻), H-17 (<i>Rec</i> ⁺)	300 µg/ml	Positive ¹	(Sakagami et al., 1988)	Dose-dependent DNA-damage. At minimum inhibitory concentration REC-assay more sensitive than Ames test (see above).
	L-arabinose resistance forward mutation test	<i>S. typhimurium</i> : BA9, BA13	62 - 250 nmoles/ml (6.2 - 25 µg/ml)	Negative ¹⁵ Positive ¹⁵	(Ruiz-Rubio et al., 1985)	
	Forward mutation assay	Mouse lymphocytes: L5178Y TK+/-	8 µg/ml	Positive ²	(McGregor et al., 1988b)	Reliable study, conclusion comprehensible.
	Forward mutation assay	Chinese hamster ovary cells	40.8µM (4.08 µg/ml)	Negative ¹	(Slesinski et al., 1983)	Lack of mutagenic activity considered to be due to reaction of glutaraldehyde with proteins in cell membrane, cytosol.
	Sister chromatid exchange	Chinese hamster ovary cells	2.5 µM (.25 µg/ml)	Negative ¹	(Slesinski et al., 1983)	Lack of mutagenic activity considered to be due to reaction of glutaraldehyde with proteins in cell membrane, cytosol.
	Sister chromatid exchange	Chinese hamster ovary cells	0.5 - 16 µg/ml	Negative/positive ² Positive ³	(Galloway et al., 1985)	Study performed in 2 laboratories aimed to develop sensitive test protocol. 11-16 µg/ml, with S9 positive (at least with one dose) results in both laboratories. 0.36-16 µg/ml, without S9 results not consistent.
	Chromosomal aberrations	Chinese hamster ovary cells	0.5 - 30 µg/ml	Negative/positive ² Negative ³	(Galloway et al., 1985)	Study performed in 2 laboratories aimed to develop sensitive test protocol. 1-16 µg/ml, with S9 negative results in both laboratories. 0.3-30 µg/ml, without S9 results not consistent.
	Alkaline elution assay	Human TK6 lymphoblasts	25 µM (0.25 µg/ml) ²	Positive ²	(St. Clair et al., 1991)	Linear increase in DNA cross linking between 1-25 µM. At 20 µM 10 % survival only.
	TK6 mutation assay	Human TK6 lymphoblasts	20 µM (2 µg/ml)	Positive	(St. Clair et al., 1991)	Majority of trifluorothymidine resistant colonies displayed normal growth, slow-growing colonies small contribution to overall mutant fraction.
Glutaraldehyde [05.149] continued	Unscheduled DNA synthesis	Primary rat hepatocytes	51 µM (5.1 µg/ml)	Negative ¹	(Slesinski et al., 1983)	Lack of mutagenic activity considered to be due to reaction of glutaraldehyde with proteins in cell membrane, cytosol.

Table IV.4: GENOTOXICITY (*in vitro*)

Chemical Name [FL-no:]	Endpoint	Test Object	Concentration / Dose	Result	Reference	Comments
	Unscheduled DNA synthesis	Rat hepatocytes	100 µM (10 µg/ml)	Positive ²	(St. Clair et al., 1991)	Significant increase over controls at 100 µM, this concentration tolerated without morphological signs of toxicity.
(Adipic acid [08.026])	Ames test	<i>E. coli</i> WP2 <i>uvrA</i>	5000 µg/plate	Negative ¹	(Shimizu et al., 1985)	
	Ames test	<i>S. typhimurium</i> TA1535, TA100, TA1537, TA1538, TA98, <i>E. coli</i> WP2 <i>uvrA</i>	10 mg/plate (10000 µg/plate)	Negative ¹	(Prival et al., 1991)	
	Ames test (preincubation method)	<i>S. typhimurium</i> TA1535, TA100, TA1537, TA1538, TA98	5000 µg/plate	Negative ¹	(Shimizu et al., 1985)	
(Dibutyl sebacate [09.474])	Ames test	<i>S. typhimurium</i> TA1535, TA100, TA1537, TA1538, TA98	3.6 mg/plate (3600 µg/plate)	Negative ¹	(Wild et al., 1983)	
(Ethyl brassylate [09.533])	Ames test	<i>S. typhimurium</i> TA1535, TA100, TA1537, TA1538, TA98	3.6 mg/plate (3600 µg/plate)	Negative ¹	(Wild et al., 1983)	
(Prop-1-ene-1,2,3-tricarboxylic acid [08.033])	Ames test	<i>S. typhimurium</i> TA100, TA1535, TA1537, TA98	20000 µg/plate	Negative ¹	(Andersen and Jensen, 1984a)	
5,6-Dimethyl-tetrahydro-pyran-2-one [10.168]	Ames test	<i>S. typhimurium</i> TA98, TA100, TA102, TA1535, TA1537	5000 microgram/plate	Negative ¹	(Uhde, 2004a)	Test performed both in the incorporation and preincubation assays.
Succinic acid, disodium salt [08.113]	Ames test	<i>S. typhimurium</i> TA97, TA94, TA98, TA100, TA1535, and TA1537	5000 microgram/plate	Negative ³	(Ishidate et al., 1984) in (OECD, 2003)	GLP-study according to OECD TG 471.
	Ames test	<i>S. typhimurium</i> TA97, TA102	10000 microgram /plate	Negative ¹	(Fujita et al., 1994) in (OECD, 2003)	GLP-study according to OECD TG 471.
	Chromosomal aberrations (polyploidy)	Chinese hamster lung cells	15000 microgram/ml	Equival ²	(Ishidate et al., 1984) in (OECD, 2003)	GLP-study according to OECD TG 473.
(Disodium succinate hexahydrate)	Ames test	<i>S. typhimurium</i> TA97, TA94, TA98, TA100, TA1535, and TA1537	5000 microgram/plate	Negative ¹	MHLW, Japan 2002 in (OECD, 2003)	
	Chromosomal aberrations (polyploidy)	Chinese hamster lung cells	5000 microgram/ml	Negative ¹	MHLW, Japan 2002 in (OECD, 2003)	

NR: Not reported.

¹ With and without S-9 metabolic activation.

² Without S-9 metabolic activation.

³ With S-9 metabolic activation.

⁴ Presence or absence of metabolic activation not specified.

⁵ Anti-mutagenic effects study.

⁶ Presence or absence of metabolic activation not specified.

⁷ 4,5-dimethyl-3-hydroxy-2,5-dihydrofuran-2-one did not form DNA adducts, but 2,5-DMHF does. Study addresses mechanism of chemical reaction of 2,5-dimethyl-4-hydroxy-3(2H)-furanone with DNA.

⁸ The concentrations used were 10-fold higher than that of spontaneous revertants.

⁹ The test substance had a severe toxic effect on phage yield.

¹⁰ Weak positive results were detected.

¹¹ The test substance induced statistically significant levels of unscheduled DNA synthesis in two of the six dose levels tested. Therefore, the test substance is considered a weak mutagen.

¹² This test compared the results at two different laboratories. Results were equivocal at Case Western Reserve University, while they were positive at Microbiological Associates.

¹³ Article presents the results from three different laboratories. Results were positive in both water and ethanol; however, it was concluded that TA102 is not sufficiently matured to be employed routinely.

¹⁴ Maximum non-toxic dose.

¹⁵Results were negative in BA9, not BA13.

In vivo mutagenicity/genotoxicity data are available for six candidate substances of the present Flavouring Group Evaluation from chemical groups 9, 13 and 30 of the present Flavouring Group Evaluation and for eight supporting substances evaluated by JECFA at the 49th and 53rd meetings (JECFA, 1998a; JECFA, 2000c). Supporting substances are listed in brackets.

Table IV.5: Genotoxicity Studies (*In Vivo*)

Chemical Name [FL-no:]	Test system	Test Object	Route	Dose	Result	Reference	Comments
(Butyro-1,4-lactone [10.006])	<i>In vivo</i> Bone- marrow micronucleus assay	B6C3F1 mice	Single dose <i>via</i> intraperitoneal injection	80 % of LD ₅₀	Negative	(Salamone et al., 1981)	Limited relevance because PCE/NCE ratio was not reported, thus it is not clear if the test substance reached the bone marrow.
	<i>In vivo</i> Bone- marrow micronucleus assay	CD-1 mice		0.11-0.44 ml/kg (110 – 440 mg/kg)	Negative	(Tsuchimoto and Matter, 1981)	Limited relevance because PCE/NCE ratio was not reported, thus it is not clear if the test substance reached the bone marrow.
	<i>In vivo</i> micronucleus assay	Mice (B6C3F1/BR hybrid)		80 % of LD ₅₀	Negative	(Katz et al., 1981)	Limited relevance because PCE/NCE ratio was not reported, thus it is not clear if the test substance reached the bone marrow.
	<i>In vivo</i> sperm abnormality	Mice (CBA X Balb/c)F1	Daily exposure for five days <i>via</i> intraperitoneal injection	0.1-1.0 mg/kg bw/day	Negative	(Topham, 1980)	Sperm head abnormality test does not make use of a genetic endpoint.
	<i>In vivo</i> sex-linked recessive test	<i>D. melanogaster</i>	A: <i>via</i> diet B: injection	A: 20000 or 28000 ppm B: 15.000 ppm	Negative	(Fouremant et al., 1994)	Study in compliance with OECD 477.
(Hexano-1,5-lactone [10.010])	Chromosomal aberration <i>in vivo</i>	Rat bone-marrow cell		NR	Negative ¹	(Kawachi et al., 1980b)	Summary of results on 186 compounds. No details on methods, concentrations and data given, results cannot be validated.
(Undecano-1,4-lactone [10.002])	<i>In vivo</i> mouse micronucleus test	2-6 ddY male mice	<i>Via</i> intraperitoneal injection	250-2000 mg/kg	Negative	(Hayashi et al., 1988)	Single application, only one sampling time. Not in compliance with current OECD 474.
2-Butoxyethan-1-ol [02.242]	<i>In vivo</i> mouse micronucleus test	Mouse bone marrow	Single dose <i>via</i> intraperitoneal injection	1000 mg/kg	Negative	(Elias et al., 1996)	Reliable report, decreased PCE/NCE ratio demonstrates bioavailability of compound at target compartment. Conclusion comprehensible.
	<i>In vivo</i> mouse micronucleus test	Mouse bone marrow	3 doses <i>via</i> intraperitoneal injection	450 mg/kg	Negative	(NTP, 2000b)	NTP-study within mutagenicity testing program. Reliable study, conclusion comprehensible.
	<i>In vivo</i> micronucleus test	Rat bone marrow	3 doses <i>via</i> intraperitoneal injection	550 mg/kg	Negative	(NTP, 2000b)	NTP-study within mutagenicity testing program. Reliable study, conclusion comprehensible.
	<i>In vivo</i> DNA adducts	Rat brain, kidney, liver, spleen and testes	Single dose <i>via</i> oral route	120 mg/kg	Negative	(Keith et al., 1996a)	The method (based on ³² P-postlabelling) is aimed at detecting hydrophobic DNA

Table IV.5: Genotoxicity Studies (*In Vivo*)

Chemical Name [FL-no:]	Test system	Test Object	Route	Dose	Result	Reference	Comments
	<i>In vivo</i> DNA methylation	Rat brain, kidney, liver, spleen and testes,	<i>Via</i> oral route	NR	Negative	(Keith et al., 1996a)	adducts resulting from CytP450 induction, not from binding of 2-butoxyethan-1-ol to DNA . Supplementary information not directly relevant for genotoxicity assessment.
	<i>In vivo</i> DNA adducts	Mouse	<i>Via</i> oral route	NR	Negative	(Keith et al., 1996a)	Detection of hydrophobic DNA adducts such as modified nucleotides with aliphatic side chains.
	<i>In vivo</i> DNA methylation	Mouse	<i>Via</i> oral route	NR	Negative	(Keith et al., 1996a)	Supplementary information not directly relevant for genotoxicity assessment.
	<i>In vivo</i> tumour formation	Mouse	Daily dose for two weeks <i>via</i> oral route	120 mg/kg/day	Inconclusive	(Keith et al., 1996a)	No difference in tumor incident observed. However no conclusion on the oncogenic potential of 2-butoxyethan-1-ol can be drawn because of the limitations of the experimental protocol (treatment, sample size, duration of the study, reporting, etc.).
Butane-1,3-diol [02.132]	<i>In vivo</i> cytogenetic assay	Rat femur bone marrow	<i>Via</i> diet ²	5, 10, 24 %	Negative	(Hess et al., 1981)	F1A, F2A, F3A generations in a multigeneration reproductive toxicity study. PCE/NCE ratio was not reported, thus it is not clear if the test substance reached the bone marrow.
	<i>In vivo</i> dominant lethal assay	Rat	Animals exposed for eight weeks <i>via</i> diet	5, 10, 24 %	Negative	(Hess et al., 1981)	F1B generation in a multigeneration reproductive toxicity study.
(3,7-Dimethyloctane-1,7-diol [02.047])	<i>In vivo</i> micronucleus test	Mouse		516, 860, 1204 mg/kg	Negative	(Wild et al., 1983)	Limited quality since only a single sampling time (30 hours after treatment) was used and PCE/NCE ratio was not reported. Therefore it is not clear whether the substance had reached the bone marrow.
	<i>In vivo</i> Basc test	<i>D. melanogaster</i>		10 mM (1743 µg/ml)	Negative	(Wild et al., 1983)	A single dose was tested in one experiment. Method not described in detail.
(3,7-Dimethyl-7-hydroxyoctanal [05.012])	<i>In vivo</i> Basc test	<i>D. melanogaster</i>		37 mM (6374 µg/ml)	Negative	(Wild et al., 1983)	A single dose was tested in one experiment. Method not described in detail.
	<i>In vivo</i> micronucleus test	Mouse		345, 603, 861 mg/kg	Negative	(Wild et al., 1983)	Limited quality since only a single sampling time (30 hours after treatment) was used and PCE/NCE ratio was not reported. Therefore it is not

Table IV.5: Genotoxicity Studies (*In Vivo*)

Chemical Name [FL-no:]	Test system	Test Object	Route	Dose	Result	Reference	Comments
(1,1-Dimethoxy-3,7-dimethyloctan-7-ol [06.011])	<i>In vivo</i> Basc test	<i>D. melanogaster</i>		25 mM (5459 µg/ml)	Negative	(Wild et al., 1983)	clear whether the substance had reached the bone marrow. A single dose was tested in one experiment. Method not described in detail.
	<i>In vivo</i> micronucleus test	Mouse		327, 545, 763 mg/kg	Negative	(Wild et al., 1983)	Limited quality since only a single sampling time (30 hours after treatment) was used and PCE/NCE ratio was not reported. Therefore it is not clear whether the substance had reached the bone marrow.
Malonic acid [08.053]	<i>In vivo</i> mutagenicity assay	Rat hepatocytes	400 mg/kg/day exposure for 6 weeks <i>via</i> diet	4000 ppm	Negative	(Ito et al., 1988)	GST-P foci assay following diethyl nitrosamine exposure. Reliable study, conclusion comprehensible.
Glutaric acid [08.082]	<i>In vivo</i> bone marrow chromosomal aberrations	Rat bone marrow	Single dose <i>via</i> oral gavage	Males: 2750 mg/kg Females: 1375 mg/kg	Negative	(San Sebastian, 1989a)	Reliable study, e.g. cells with gaps excluded. Selected copy of report without data tables.
Glutaraldehyde [05.149]	<i>In vivo</i> chromosomal aberration	Rat bone marrow	Single dose <i>via</i> oral gavage	Males: 120 mg/kg/bw Females: 80 mg/kg/bw	Negative	(Vergnes and Morabit, 1993a)	Study in compliance with international (FDA, TSCA, OECD) GLP guidelines. Selected copy of report (12 of 100 pages) available.
	<i>In vivo</i> chromosomal aberration	Rat bone marrow	A single dose or daily for five days <i>via</i> oral gavage	Single dose: 0.55 ml/kg (males), 0.4 ml/kg (females) of a 6, 12 or 36 % solution. Repeated dose: 0.55 ml/kg (males) of a 5 % solution	Negative	(Putman, 1987)	Time points of investigation: single dose: 8, 12 hours. Repeated dose: 12hours. Well conducted study, conclusion comprehensible. Selected copy of report available.
	<i>In vivo</i> mouse blood micronucleus test	Mouse	Single dose <i>via</i> oral gavage	250 mg/kg	Negative	(Vergnes and Morabit, 1993b)	Selected pages of report available (29 of 88 pages).
	<i>In vivo</i> mouse blood micronucleus test	Mouse	Single dose <i>via</i> intraperitoneal injection	4, 8, 15 mg/kg/bw	Positive	(Noblitt et al., 1993)	Abstract, study cannot be validated.
	<i>In vivo</i> unscheduled DNA synthesis	Rat	Single dose <i>via</i> oral gavage	30, 150, 600 mg/kg	Negative	(Mirsalis et al., 1989)	Reliable part of <i>In vivo</i> tumour formation study, conclusion comprehensible.
	<i>In vivo</i> SLRL test	<i>D. melanogaster</i>	Three day exposure <i>via</i> diet	3500 ppm	Negative	(Zimmering et al., 1989)	Study in compliance with OECD 477.
	<i>In vivo</i> SLRL test	<i>D. melanogaster</i>	Single dose <i>via</i> intraperitoneal injection three day exposure <i>via</i> diet	Injection: 4000 ppm Diet: 10,000 ppm	Negative	(Yoon et al., 1985)	Study in compliance with OECD 477.
(Adipic acid [08.026])	<i>In vivo</i> chromosomal nondisjunction	<i>D. melanogaster</i>		4000 ppm	Negative	(Ramel and Magnusson, 1979)	
Diethyl adipate [09.348]	<i>In vivo</i> dominant lethal assay	Mouse	(Single) 1460 mg/kg dose <i>via</i> intraperitoneal injection)	1.46 ml/kg	Negative	(Singh et al., 1975)	Reliable study, conclusion comprehensible.

Table IV.5: Genotoxicity Studies (*In Vivo*)

Chemical Name [FL-no:]	Test system	Test Object	Route	Dose	Result	Reference	Comments
(Dibutyl sebacate [09.474])	<i>In vivo</i> micronucleus test	Mouse		943, 1886, 2829 mg/kg	Negative	(Wild et al., 1983)	Limited quality since only a single sampling time (30 hours after treatment) was used and PCE/NCE ratio was not reported. Therefore it is not clear whether the substance had reached the bone marrow.
	<i>In vivo</i> Basc test	<i>D. melanogaster</i>		19 mM (4642 µg/ml)	Negative	(Wild et al., 1983)	A single dose was tested in one experiment. Method not described in detail.

NR: Not reported.

¹Presence or absence of metabolic activation not specified.

²Length of exposure not specified in report. Cytogenetic assay conducted on F1A, F2A and F3A generations of a multiple generation study.

PART I—THE FEMA GRAS ASSESSMENT PROGRAM

I. Chemical identity

This summary presents the key scientific data relevant to the safety evaluation of 44 lactones used as flavour ingredients (see Appendix A). Lactones are cyclic esters which form by intramolecular cyclization of the corresponding hydroxycarboxylic acids. Most naturally occurring lactones are either five-membered (γ) or six-membered (δ) rings formed from saturated or unsaturated hydroxylated fatty acids. The group of lactones reviewed here includes those formed from the following:

- (1) aliphatic acyclic linear saturated hydroxycarboxylic acids (19; Nos 1–19)
- (2) aliphatic acyclic linear unsaturated hydroxycarboxylic acids (9; Nos 20–28)
- (3) aliphatic acyclic branched-chain hydroxycarboxylic acids (7; Nos 29–35)
- (4) alicyclic and aromatic hydroxycarboxylic acids (9; Nos 36–44)

Abbreviations: ABS = chromosome aberrations; ALP = alkaline phosphatase; ALT = alanine aminotransferase; CHO = Chinese hamster ovary; CoA_A = coenzyme A; CR = consumption ratio; CYP450 = cytochrome *P*-450; DNA = deoxyribonucleic acid; FEMA = The Flavor and Extract Manufacturers' Association; GGT = γ -glutamyl transferase; GRAS = generally recognized as safe; LD₅₀ = median lethal dose; MLA = mouse lymphoma cells; RLH = rat liver homogenate; SCE = sister chromatid exchanges; UDS = unscheduled DNA synthesis.

II. Exposure

A. Flavour use

Low molecular weight lactones (<C8) formed from acyclic hydroxycarboxylic acids (Nos 1–35) generally exhibit a sweet herbaceous aroma accompanied by a sweet caramel-like taste. Higher molecular weight lactones mainly derived from fatty acids exhibit a fatty-, peachy- or coconut-like aroma. Two alicyclic lactones (Nos 37 and 38) derived from side-chain oxidation of menthone (i.e. dehydromenthofur-lactone) and menthol (i.e., mint lactone), respectively, exhibit a peppermint flavour. Two lactones fused to an aromatic ring system, dihydrocoumarin (No. 40) and 6-methylcoumarin (No. 41) have the sweet herbaceous aroma of new-mown hay.

Lactones are usually added as flavour ingredients to foods at levels less than 20 ppm, with a range of 0.05 to 80 ppm. Maximum levels of use are between 0.1 and 500 ppm, but are generally below 50 ppm. Only three substances, γ -valerolactone (148 ppm), 6-hydroxy-3,7-dimethyl octanoic acid lactone (500 ppm) and dihydrocoumarin (165 ppm) are used at levels greater than 100 ppm. The concentrations of aliphatic lactones intentionally added to foods are similar to those which occur naturally in food. For example, low molecular weight aliphatic (<C9) lactones are found in berries, fruits and related alcoholic beverages at concentrations of less than 1.0 ppm. Higher molecular weight aliphatic lactones (>C9) are present in meat and dairy products, mainly cheese and butter, at less than 20 ppm. Highest concentrations have been detected

in coconut (97 ppm) and strawberry jam (173 ppm) (CIVO-TNO, 1994).

The aliphatic lactones having the highest reported annual volumes of use in industry surveys (NAS, 1970, 1975, 1982 and 1987) are γ - and δ -lactones formed from linear saturated hydroxycarboxylic acids. Lactones derived from aliphatic hydroxycarboxylic acids of carbon chain length from C8 to C12 account for greater than 94% of the reported annual volume in the most recent survey (NAS, 1987). Four (4) γ - and δ -lactones (γ - and δ -decalactones and γ - and δ -dodecalactones) formed from the hydroxylated C10 and C12 fatty acids make up approximately two-thirds of the annual volume (NAS, 1987). Each of these lactones has been detected as a naturally occurring component of more than 30 foods (CIVO-TNO, 1994) and was originally studied as a flavour ingredient for use in margarine.

Dihydrocoumarin (3750 kg/yr) is the only lactone derived from alicyclic or aromatic hydroxycarboxylic acids with a reported annual volume of use greater than 1000 kg (NAS, 1987). Its use as a flavour ingredient has decreased significantly since 1970, from 11,900 kg to 3750 kg. Based on a reported annual volume of 3750 kg (NAS, 1987), the estimated daily *per capita* intake ("eaters only") of dihydrocoumarin is 12 μ g/kg.

B. Natural occurrence

33 ingredients in this group (see Tables B1 and B2) have been reported to occur naturally in traditional foods, at levels between 0.001 and 200 ppm (CIVO-TNO, 1994). Four lactones formed from aliphatic acyclic hydroxycarboxylic acids with significant use as flavour ingredients (i.e. the γ - and δ -lactone of hydroxydecanoic acid and the γ - and δ -lactone of hydroxydodecanoic acid; Nos 10, 11, 15 and 16) are ubiquitous in food occurring mainly in fruits, berries, alcoholic beverages, meats and dairy products. In general, aliphatic lactones exist naturally as mixtures of enantiomers. For instance, γ - and δ -hexalactone and δ -octalactone are present in pineapple in enantiomeric ratios (S/R) of 76/24, 16/84 and 49/51, respectively (Engel *et al.*, 1989). The distribution of chiral γ -lactones in fruit (e.g. pineapple) increases in favour of the R configuration with increasing chain length (Mosandl *et al.*, 1990).

Aliphatic lactones occur naturally at highest concentrations (up to 100 ppm) in foods having a high fat content such as meat, cheese, milk and coconuts. Seven lactones derived from aliphatic acyclic hydroxycarboxylic acids have not yet been reported in food, including three ϵ -lactones (Nos 12, 17 and 32), 5-hydroxy-8-undecenoic acid δ -lactone (No. 25), and three branched-chain aliphatic lactones (Nos 29, 30 and 34). These seven lactones have minimal use as flavour ingredients (<50 kg/yr). Four lactones fused to alicyclic or aromatic ring systems (Nos 36, 40, 41 and 42), including dihydro-

coumarin and 6-methylcoumarin, have not been reported as components of food (see Table B2).

Quantitative natural occurrence data have been reported for 17 lactones formed from aliphatic acyclic hydroxycarboxylic acids and one lactone formed from alicyclic and aromatic hydroxycarboxylic acids (Stofberg and Kirschman, 1985). As represented by the consumption ratio (CR) (Stofberg and Grundschober, 1987; Stofberg and Kirschman, 1985), exposure to all but four of the 18 lactones occurs predominantly from food (i.e. CR > 1; see Tables B1 and B2). Intake of δ -nonalactone (No. 9), γ -decalactone (No. 11), γ -undecalactone (No. 13), and δ -undecalactone (No. 14) predominates from flavour use in dairy and butter flavourings (Lawrence, 1991; White and White, 1991).

III. Metabolism

A. Equilibrium between aliphatic lactones and ring-opened hydroxycarboxylic acids: effect of pH

Lactones are formed in nature by acid-catalysed intramolecular cyclization of γ - or δ -hydroxycarboxylic acids to yield five- or six-membered lactone rings (Fig. 1). In an aqueous environment, a pH-dependent equilibrium is established between the open-chain hydroxycarboxylate anion and the lactone ring. In basic media, the open-chain hydroxycarboxylate anion is favoured while in acidic media, such as in the urine, the lactone form predominates. γ -Valerolactone and γ -hexalactone have been detected in the urine of normal human adults (Zlatkis and Liebich, 1971).

When 4-hydroxybutanoic acid γ -lactone is administered intravenously (Roth and Giarman, 1966) or orally (Guidotti and Ballotti, 1970) to rats, the open-chain 4-hydroxybutanoate anion is formed in the blood and tissues. The half-life for

Fig. 1. Equilibrium of γ - and δ -lactone and hydroxycarboxylate anion.

ω -6-Hexadecenalactone	2555	92 (SIF) 96 (SIF)	0.25 1	Morgareidge, 1962 Morgareidge, 1963

*Incubation, 1 mM with simulated intestinal fluid (SIF) or rat liver homogenate (RLH).

the conversion of the lactone ring to the open-chain anion in the blood is less than 1 min. The reaction is catalysed by γ -lactonase, which shows greater activity in the plasma than in the liver or brain (Fishbein and Bessman, 1966). Hydrolysis of γ - and ϵ -aliphatic lactones and lactones formed from tertiary alcohols have been observed *in vitro* in basic simulated intestinal fluid and rat liver homogenate (see Table 1 and B3).

B. Metabolism of lactones formed from aliphatic acyclic linear saturated and unsaturated hydroxycarboxylic acids (Nos 1-28)

Linear aliphatic hydroxycarboxylic acids are hydrolysed and rapidly oxidized via the fatty acid pathway. Linear saturated 5-hydroxycarboxylic acids formed from δ -lactones are converted, via acetyl coenzyme A, to hydroxythioesters which then undergo β -oxidation and cleavage to yield an acetyl CoA fragment and a new β -hydroxythioester reduced by two carbons. Even-numbered carbon acids continue to be oxidized and cleaved to yield acetyl CoA while odd-numbered carbon acids yield acetyl CoA and propionyl CoA. Acetyl CoA enters the citric acid cycle directly while propionyl CoA is transformed into succinyl CoA which then enters the citric acid cycle. Linear saturated 4- or 6-hydroxycarboxylic acids formed from γ - or ϵ -lactones participate in the same pathway; however, loss of an acetyl CoA fragment produces an α -hydroxythioester which undergoes α -decarboxylation to yield a linear carboxylic acid and eventually carbon dioxide (Voet and Voet, 1990). In rats and dogs, $^{14}\text{C}_1$ - γ -decalactone and $^{14}\text{C}_1$ - γ -dodecalactone are metabolized in a manner similar to $^{14}\text{C}_1$ -lauric acid with approximately 75% of the labelled ^{14}C being eliminated as carbon dioxide within 48 hr (Fassett, 1961).

The metabolic fate of lactones has been extensively studied in animals, including humans. In rats, oral doses greater than 100 mg/kg of γ -butyrolactone (4-hydroxybutanoic acid lactone) were absorbed rapidly and completely from the intestinal tract (Arena and Fung, 1980; Guidotti and Ballotti,

1970; Lettieri and Fung, 1978). The majority of $^{14}\text{C}_1$ -labelled sodium 4-hydroxybutanoate administered by intravenous injection to rats was recovered as $^{14}\text{CO}_2$ within 2.5 hr (Roth and Giarman, 1965). Intermediates formed during β -oxidation of lactones have been detected in humans (Lee, 1977; Walkenstein *et al.*, 1964). (S)-3,4-Dihydroxybutyric acid, glycolic acid and 4-hydroxy-3-oxobutyric acid were present in the urine of humans given a 1.0 g oral dose of γ -butyrolactone (Lee, 1977) (Fig. 2).

γ -Butyrolactone, the only lactone in this group formed from a primary alcohol, may participate in an alternate oxidation pathway. Oxidation of γ -butyrolactone to succinate by alcohol dehydrogenase and succinic semialdehyde dehydrogenase occurs primarily in the liver (Jakoby and Scott, 1959). Succinate then participates in the citric acid cycle (Doherty and Roth, 1978; Lee, 1977; Möhler *et al.*, 1976; Walkenstein *et al.*, 1964).

If the lactone is formed from a linear hydroxycarboxylic acid containing unsaturation, cleavage of acetyl CoA units will continue along the carbon chain until the position of unsaturation is reached. If the unsaturation begins at an odd-numbered carbon, acetyl CoA fragmentation will eventually yield a Δ^3 -enoyl CoA which is converted to the *trans*- Δ^2 -enoyl CoA before entering the fatty acid pathway. If unsaturation begins at an even-numbered carbon, acetyl CoA fragmentation yields a Δ^2 -enoyl CoA product which is a substrate for further fatty acid oxidation. If the stereochemistry of the double bond is *cis*, hydration yields (R)-3-hydroxyacyl CoA which is isomerized to (S)-3-hydroxyacyl CoA by 3-hydroxyacyl CoA epimerase prior to entering into normal fatty acid metabolism (Voet and Voet, 1990).

If the lactone contains a conjugated alkene, glutathione conjugation may occur as a minor metabolic pathway. Liver glutathione levels were significantly reduced following an intraperitoneal injection of 5-hydroxy-2-hexenoic acid δ -lactone (parasorbic acid lactone) to rats (Boyland and Chasseaud, 1970). *In vitro* the reaction is catalysed by glutathione S-transferase (Chasseaud, 1979).

Fig. 2. Metabolism of γ -butyrolactone in humans.

C. Metabolism of lactones formed from aliphatic acyclic branched-chain saturated and unsaturated hydroxycarboxylic acids (Nos 29–35)

Short-chain (<C6) branched aliphatic acyclic hydroxycarboxylic acids may be excreted unchanged as the glucuronic acid conjugate, or undergo α - or β -oxidation followed by cleavage and complete metabolism to CO₂ (Voet and Voet, 1990; Williams, 1959) via the fatty acid pathway and the tricarboxylic acid cycle. Alternatively, as chain length, substitution and lipophilicity increase, the hydroxycarboxylic acid may undergo a combination of ω -, ω -1 and β -oxidation to yield polar hydroxyacid, ketoacid and hydroxydiacid metabolites which may be excreted as the glucuronic acid or sulfate conjugates in the urine and, to a lesser extent, in the faeces (Diliberto *et al.*, 1990). Methyl substituted carboxylic acids are, to some extent, ω -oxidized in animals to form diacids which can be detected in the urine (Williams, 1959). The principal metabolic pathways utilized for detoxication of branched-chain acids are influenced by the position, number, and size of alkyl substituents.

Acids with a methyl substituent located at an even-numbered carbon (e.g. 2-methylpentanoic acid or 4-methyldecanoic acid) are extensively metabolized in the fatty acid pathway to CO₂ via β -oxidation and cleavage of the longer-branched chain. If the methyl group is located at an odd-numbered carbon such as the 3-position, β -oxidation is inhibited and ω -oxidation predominates, primarily leading to polar, acidic metabolites capable of being excreted in the urine (Williams, 1959). Larger alkyl substituents (>C2) located at the α - or β -position inhibit metabolism to CO₂ (Albro, 1975; Deisinger *et al.*, 1994; Deuel, 1957), in which case there is either direct conjugation of the acid with glucuronic acid, or ω -oxidation leading to diacid metabolites which may be conjugated and excreted.

D. Metabolism of lactones formed from hydroxycarboxylic acids fused to alicyclic (4) and aromatic (5) ring systems (Nos 36–44)

1. Lactones fused to alicyclic rings (Nos 36–39). The pathways of metabolism for lactones fused to alicyclic rings depends on the size of the lactone ring (e.g. γ or δ), the degree of unsaturation and type of substitution on the ring system. If the lactone is a δ -lactone fused to an alicyclic ring (e.g. octahydrocoumarin; No. 36), it may be hydrolysed to a carboxylic acid containing an odd number (3) of carbons in the side-chain. β -Oxidation of the side-chain of octahydrocoumarin and cleavage yields 3-hydroxycyclohexanecarboxylic acid which may be subsequently aromatized to a benzoic acid derivative and excreted mainly as the hippuric acid.

In perfused rat liver, cyclohexanecarboxylic acid is primarily metabolized to hippuric acid. Small amounts of cyclohexylcarbonyl glucuronide, hexahydrohippuric acid, 3,4,5,6-tetrahydrohippuric acid, unchanged cyclohexanecarboxylic acid and benzoic acid also were detected (Brewster *et al.*, 1977b). Benzoyl glucuronide was found in the bile of rats as an *in vivo* metabolite of cyclohexanecarboxylic acid (Brewster *et al.*, 1977a).

If alkyl substituents are present on the alicyclic ring, hydrolysis may be followed by excretion in the urine or oxidation of ring substituents or the ring itself to yield polar hydroxylated metabolites, which may also be excreted primarily in the urine. The lactone ring in dehydromenthofurolactone (No. 37) or mintlactone (No. 38) is expected to hydrolyse to the enolic form of the ketocarboxylic acid, 9-carboxypulegone or 9-carboxymenthol, respectively. The ketocarboxylic acid or hydroxycarboxylic acid may be excreted unchanged as the glucuronic acid conjugate or undergo side-chain oxidation to yield hydroxylated metabolites which may also be excreted. The structurally related detoxication metabolites 3-hydroxymenthofurolactone, its ring-

opened form 9-carboxypulegone, and the hydroxylated metabolites of 9-carboxypulegone have been detected in the urine of rats given pulegone or menthofuran (Madyastha and Raj, 1993).

2. *Lactones fused to aromatic rings* (Nos 40–44). Unlike aliphatic lactones which are readily hydrolysed to the corresponding hydroxy acids *in vivo* (Oser, 1962 and 1963), fused ring aromatic lactones such as coumarin are relatively stable so that oxidation competes favourably with hydrolysis of the lactone ring. Increased stability may result from extended conjugation of the aromatic ring with the α,β -unsaturated lactone ring present in coumarin derivatives. Despite the similarities in their names, dihydrocoumarin is not a member of the class of aromatic coumarin derivatives. Dihydrocoumarin lacks α,β -unsaturation in the lactone ring (see Appendix A, Fig. A4), which is a key structural feature to the metabolism of coumarin. Coumarin is principally metabolized in humans, cynomolgus monkeys and baboons by electrophilic substitution (i.e. 7-hydroxylation), and in rats and several other species by epoxidation of the alkene function to form mainly 3-hydroxycoumarin (e.g. Egan *et al.*, 1990; Van Iersel *et al.*, 1994). The absence of a double bond in dihydrocoumarin precludes the formation of the reactive epoxide and subsequent metabolites. Therefore, the metabolism of dihydrocoumarin would more closely resemble that of an aliphatic δ -lactone than coumarin.

In animals, dihydrocoumarin is expected to hydrolyse to the corresponding ring-opened hydroxycarboxylic acid, *o*-hydroxyphenylpropionic acid (*o*-HPPA) (Fig. 3). In a report containing limited experimental data (Furuya, 1958), a "considerable dose" of dihydrocoumarin was given orally to rabbits. Principle urinary metabolites identified by qualitative thin layer chromatography included *o*-HPPA and the glycine conjugate of *o*-HPPA. Minor urinary metabolites included *o*-coumaric

acid, *o*-coumarylglycine, coumarin, 7-hydroxycoumarin and 3-hydroxycoumarin. Dihydrocoumarin undergoes ring opening hydrolysis to *o*-HPPA when incubated with rat caecal extract (Scheline, 1968).

Following hydrolysis, *o*-HPPA may undergo β -oxidation to yield *o*-hydroxybenzoic acid (salicylic acid), which is excreted primarily in the urine unchanged or as the glycine conjugate (Oser, 1962 and 1963) (Fig. 3). In humans, the structurally related acids 3-phenylpropionic acid (Pollitt, 1974) and 3-phenylpropenoic acid (i.e. cinnamic acid) (Williams, 1959) undergo β -oxidation and cleavage to yield benzoic acid which is excreted predominantly in the urine as hippuric acid. In rats and mice, cinnamic acid is also metabolized mainly to hippuric acid (Nutley *et al.*, 1994); in rats, however, *o*-methoxycinnamic acid metabolizes mainly to the β -hydroxy derivative [i.e. 3-hydroxy-3-(*o*-methoxyphenyl) propionic acid] suggesting that oxygenated substituents at the *ortho* position may inhibit complete β -oxidation in rats (Samuelson *et al.*, 1986).

It is anticipated that man will hydrolyse dihydrocoumarin to form the corresponding hydroxyacid, *o*-HPPA. The acid may either be conjugated with glycine prior to excretion or β -oxidized and cleaved to yield *o*-hydroxybenzoic acid (i.e. salicylic acid) (Fig. 3).

Unlike dihydrocoumarin, 6-methylcoumarin (No. 41) is a methyl substituted coumarin ring system which is expected to metabolize via methyl group oxidation to yield the corresponding aromatic carboxylic acid or coumarin ring oxidation. In the latter case, oxidation of the benzene ring (i.e. 7-hydroxylation) or the lactone ring alkene (i.e. 3,4-epoxidation) is possible. Compared with other metabolic pathways, 6-methylcoumarin is expected to exhibit an increased relative rate of benzene ring hydroxylation at the C7 position associated with the presence of a methyl substituent (Lake *et al.*, 1994a).

The demethylated analogue coumarin is rapidly absorbed and metabolized in humans (Cohen,

Fig. 3. Proposed metabolism of dihydrocoumarin in humans.

1979). 7-Hydroxycoumarin is the principle metabolite in humans and other primates (Cholerton *et al.*, 1992; Egan *et al.*, 1990; Rautio *et al.*, 1992; Shilling *et al.*, 1969; Waller and Chasseaud, 1981) formed by first pass metabolism in the liver (van Iersel *et al.*, 1994). 7-Hydroxycoumarin is then rapidly conjugated with glucuronic acid (Ritschel *et al.*, 1977) and excreted in the urine. 7-Hydroxylation of coumarin is catalysed by cytochrome P450 isoenzymes 2A6 (CYP2A6) and 2B6 (CYP2B6). Gene subfamilies CYP2A and CYP2B, which are expressed to form these enzymes have been isolated from human hepatic mRNA derived from chromosome 19 (Forrester *et al.*, 1992; Miles *et al.*, 1990). Volunteers excreted varying levels of 7-hydroxycoumarin (Cholerton *et al.*, 1992; Rautio *et al.*, 1992; Van Iersel *et al.*, 1994) suggesting that some inter-individual variation may exist for gene expression of CYP2A6 (Miles *et al.*, 1990; Pearce *et al.*, 1992; Yamano *et al.*, 1990; Yamazaki *et al.*, 1992).

In the alternate 3-hydroxylation pathway, which predominates in rats, coumarin is oxidized via a 3,4-epoxide intermediate to yield mainly *o*-hydroxyphenylacetic acid (*o*-HPPA). This pathway may compete favourably in humans at high substrate concentrations (Fentem and Fry, 1992; van Iersel *et al.*, 1994), presumably when CYP2A6 approaches saturation or when gene expression limits production of CYP2A6. *o*-Hydroxyphenylacetic acid (*o*-HPPA) accounted for only 1–6% of a 200 mg dose of coumarin given to humans (Shilling *et al.*, 1969). In rats, coumarin is predominantly oxidized to *o*-HPPA, presumably via a 3,4-epoxide which in part reacts with glutathione at the α -position (Huwer *et al.*, 1991). Additionally, the epoxide may bind covalently to cytoplasmic proteins (Lake *et al.*, 1989; Peters *et al.*, 1991), form a 3,4-diol, or rearrange to yield 3-hydroxycoumarin (Lewis *et al.*, 1994).

It is anticipated that humans will metabolize 6-methylcoumarin via methyl group oxidation to the corresponding benzoic acid derivative which may also be readily excreted. Alternatively, 6-methylcoumarin may undergo ring hydroxylation to form the corresponding 7-hydroxy metabolite followed by excretion as the glucuronic acid conjugate. Metabolism via the 3,4-epoxide at high dose levels constitute, at most, a minor pathway, even in individuals exhibiting decreased activity of CYP2A6.

Phthalides are lactones formed from intramolecular cyclization of *o*-hydroxyphenylacetic acid. Hydrolysis of α -alkenyl substituted phthalides (Nos 42 and 43) would yield the enol form of the corresponding ketocarboxylic acid. The benzoic acid moiety may conjugate with glycine and be excreted mainly as the hippurate, and the ketone function may be reduced to the corresponding alcohol and be excreted as the glucuronic acid conjugate. In animals, mitochondrial acid:CoA ligases activate ben-

zoates to form an intermediate CoA thioester which reacts with the amino acids glycine and glutamine. The resulting glycine conjugate of benzoic acid is efficiently removed from circulation during a single pass through the kidney (Killenberg and Webster, 1980). The phenylketone produced by hydrolysis may be reduced to the corresponding alcohol by aromatic ketone reductase (Felsted and Bachur, 1980). Reduction of other aromatic ketones (e.g. acetophenone) occurs stereoselectively (Culp and McMahon, 1968). However, it is difficult to predict stereospecificity of the reaction since aromatic ketone reductase consists of multiple enzymes with different absolute stereospecific or stereocatalytic properties. It is anticipated that humans will hydrolyse phthalides to their corresponding ketoacids, which may form their corresponding hippurate and be excreted in the urine or undergo ketone reduction to yield an alcohol which may be excreted as the corresponding glucuronic acid conjugate.

IV. Toxicology

A. Acute oral toxicity

In general, lactones formed from aliphatic acyclic hydroxycarboxylic acids (Nos 1–35) exhibit very low acute oral toxicity. Oral LD₅₀ values greater than 1000 mg/kg have been reported for 28 of the 35 lactones (see Table B3) in this group. The majority of LD₅₀ values are greater than 5000 mg/kg. The four lactones (Nos 36–39) fused to alicyclic rings have LD₅₀ values which range from a low of 530 mg/kg for mintlactone (No. 37) to more than 5000 mg/kg for sclareolide (No. 39). The five lactones fused to benzene rings (Nos 40–44) have LD₅₀ values greater than 1000 mg/kg (see Table B4).

B. Subchronic and chronic oral toxicity studies

Lactones formed from 6 linear saturated, two linear unsaturated, and two branched-chain aliphatic acyclic hydroxycarboxylic acids have been subjected to oral subchronic or chronic toxicity studies in rodents (see Section IV, B.1–B.5 below and Table B3). γ -Butyrolactone has been used therapeutically in humans as a sedative (Boncinelli *et al.*, 1971; Hunter *et al.*, 1971; Laborit *et al.*, 1960; Mamelak *et al.*, 1986), in the treatment of alcohol dependency (Ferrara *et al.*, 1992), and was the subject of a recent 2-year carcinogenicity bioassay (NTP, 1992).

One alicyclic lactone dehydromenthofuroolactone has also been subjected to an oral subchronic study (Table B4). Subchronic and chronic toxicity studies have been performed for dihydrocoumarin and 6-methylcoumarin while a single subchronic study exists for 3-propylidenephthalide (see Sections IV, B.6–B.8 below and Table B4). Dihydrocoumarin has also been the subject of a recent 2-year carcinogenicity bioassay (NTP, 1992). In all of these

studies, no-adverse-effect levels were at least 1000 times, and in most cases at least 10,000 times the respective daily *per capita* intakes ("eaters only") from use of these lactones as flavour ingredients.

1. Lactones formed from aliphatic acyclic linear saturated hydroxycarboxylic acids (Nos 1–19)

Subchronic and/or chronic studies have been performed using γ -lactones formed from C4, C5, C9 and C11 linear saturated hydroxycarboxylic acids (Table B3). No dose-related effects were reported when rats were maintained on diets providing an average daily intake of 49 mg γ -valerolactone/kg for 90 days (Oser *et al.*, 1965) or 500 mg/kg for 14 wk (Hagan *et al.*, 1967); 62.8 mg γ -nonalactone/kg for 90 days (Oser *et al.*, 1965) or 250 mg/kg for 1.5 to 2 years (Bar and Griepentrog, 1967); 16.5 mg γ -undecalactone/kg for 90 days (Oser *et al.*, 1965), 166 mg/kg for 130 days (Galea, 1965), or 250 mg/kg for 1.5 to 2 years (Bar and Griepentrog, 1967). No effects were observed in a 49-week study in rats or a 38-week study in dogs when a mixture of δ -lactones (δ -decalactone and δ -dodecalactone) was added to the diet of test animals. The mixture provided average daily intakes of δ -decalactone and δ -dodecalactone of 150 mg/kg and 300 mg/kg, respectively, to rats, and 75 mg/kg and 150 mg/kg, respectively to dogs (Wilson, 1961a). No adverse effects were reported when γ -butyrolactone was administered daily by gavage for 13 wk to mice or rats at a dose level of 112 mg/kg or 131 mg/kg, respectively (NTP, 1992). The intake levels that produced no effects in subchronic studies are greater than 10,000 times the daily *per capita* intake ("eaters only") from use of the respective lactone as a flavour ingredient or from exposure as a natural component of food.

A mixture composed primarily of aliphatic carboxylic acids and lactones was added to the diet of a limited number of rats (four males, three females) at a level calculated to result in the average daily intake of 100 mg γ -butyrolactone/kg and 32 mg/kg each for δ -octalactone, γ -nonalactone, γ -decalactone, γ -undecalactone and γ -dodecalactone for 4 to 6 months (Wilson, 1961b). Five succeeding generations were maintained on the same dietary regimen. Histopathological examinations of all treated animals revealed no effects. Although the validity of the results of the study are of limited value based on the small number of animals in the study (D. Fassett, unpublished report to RIFM, 1961), the results are consistent with those in feeding studies for individual lactone components reported above (i.e. γ -butyrolactone, γ -nonalactone, γ -decalactone).

2. Lactones formed from aliphatic acyclic linear unsaturated hydroxycarboxylic acids (Nos 20–28)

Lactones derived from the linear unsaturated carboxylic acids, 4-hydroxy-3-pentenoic acid or 5-hydroxy-2,4-decadienoic acid have been added to

the diet of rats for 90 days at levels calculated to provide an average daily intake of 17.4 mg/kg (Shellenberger, 1971) or 12.1 mg/kg, respectively (Cox, 1974). The only effect reported in either study was an increase in absolute liver and kidney weights in animals fed 4-hydroxy-3-pentenoic acid lactone. However, relative organ weights were unchanged and there was no evidence of histopathology in any organs.

4-Hydroxy-3-pentenoic acid is the enolic form of laevulinic acid (4-ketopentanoic acid) which would form on *in vivo* hydrolysis of the lactone. Humans have been given oral doses of approximately 40 or 80 mg/kg of laevulinic acid in fruit juice daily for 30 days. Based on biweekly measurements of physical well-being, urinalysis and clinical chemistry parameters no effects were reported (Tischer, 1942). These intake levels that resulted in no adverse effects are greater than 100,000 times the daily *per capita* intake ("eaters only") of 4-hydroxy-3-pentenoic acid lactone (0.08 μ g/kg) or 5-hydroxy-2,4-decadienoic acid lactone (0.002 μ g/kg) from use as flavour ingredients.

3. Lactones formed from aliphatic acyclic branched-chain hydroxycarboxylic acids (Nos 29–35)

No effects were reported when the branched-chain γ -lactone 5-ethyl-3-hydroxy-4-methyl-2(5H)-furanone (No. 34) was fed to rats at levels calculated to provide average daily intakes of 1.29 mg/kg (males) or 1.47 mg/kg (females) for 90 days (Posternak *et al.*, 1969). No toxic or carcinogenic effects were observed when rats were maintained on diets containing 4,5-dimethyl-3-hydroxy-2,5-dihydrofuran-2-one (No. 35) at levels calculated to provide an average daily intake up to 46 mg/kg for 13 wk (Mundy and Kirkby, 1971) or 1 year (Mundy and Kirkby, 1973). The intake levels that produced no effects are greater than 10,000 times the daily *per capita* intake ("eaters only") of 0.1 mg/kg from use of 5-ethyl-3,4-dihydroxy-3-methyl-2-pentenoic acid lactone or 0.002 μ g/kg 5-methyl-3,4-dihydroxy-3-methyl-2-pentenoic acid lactone from use as flavour ingredients.

4. Results of 2-year NTP bioassay with γ -butyrolactone

A chronic study of γ -butyrolactone (4-hydroxybutanoic acid lactone, No. 1) was conducted by the National Toxicology Program (NTP, 1992). The standard NTP protocol was used with F344 rats and B6C3F₁ mice. Groups of 50 male rats were administered γ -butyrolactone in corn oil by gavage in doses of 0, 112 and 225 mg/kg/day, 5 days per week, for 2 years. The same dosage schedule and sample preparation were used for female rats administered 0, 225 and 450 mg/kg/day, and for both sexes of mice administered 0, 262 and 525 mg/kg/day. Decreased body weight was reported in the high dose group of female rats and all of the test

mice. Increased mortality among the high-dose group of male mice was partially attributed to fighting on emergence from 4-hydroxybutanoic acid lactone sedation. There was no difference in survival between control and treated female mice.

Observations included statistically significant dose-related decreases in the incidence of mononuclear cell leukaemia in male rats; mammary and pituitary gland cysts and mammary gland fibroadenomas in female rats; and hepatocellular neoplasms in male mice. Male mice exhibited a statistically significant increase in the incidence of adrenal medulla hyperplasia in the low-dose group only, and an increase in the incidence of benign or malignant pheochromocytoma. The latter was not statistically significant ($P = 0.092$) and occurred only at the low dose. The lack of a dose-response relationship for these effects was postulated (NTP, 1992) to be due to the increased mortality of the high dose mice due to fighting, which prevented a greater portion of the group from receiving sample doses for a duration which would be sufficient for tumour development.

The NTP report concluded the following: "Under the conditions of these 2-year gavage studies, there was no evidence of carcinogenicity of γ -butyrolactone in male F344 rats given 112 or 225 mg/kg or in female rats given 225 or 450 mg/kg in corn oil. There was equivocal evidence of carcinogenic activity γ -butyrolactone in male B6C3F₁ mice based on marginally increased incidences of adrenal medulla pheochromocytomas and hyperplasia in the low-dose group. The sensitivity of the study in male mice to detect a carcinogenic effect was reduced by the low survival of the high-dose group associated with fighting. There was no evidence of carcinogenic activity of γ -butyrolactone in female B6C3F₁ mice receiving 262 or 525 mg/kg in corn oil."

The NTP hypothesized that the incidence of benign and malignant pheochromocytomas in male

mice would have been statistically significant ($P < 0.05$) at both dose levels if a sufficient number of animals in the high-dose group had survived long term. However, if a comparison is made between the control and treated animals that survived longer than the period of onset of neoplasms (i.e. > 582 days), there is no evidence to support the NTP hypothesis. All of the reported adrenocortical adenomas (three) and benign (five) and malignant (one) pheochromocytomas were identified in low-dose male mice surviving at least 582 days. The percentage of each group surviving at least 582 days of the study is given in Table 2. The incidence (4.6%) of pheochromocytomas observed in the control and high dose groups of male B6C3F₁ mice receiving a corn oil vehicle by gavage is within the historical range of 0–6% (NTP, 1992). Thus, taking into account the survival rates in groups of control and treated male mice, it is unlikely that the incidence of the tumours is related to the administered dose of the γ -butyrolactone.

No record is available for the onset of adrenal medulla hyperplasia. However, an estimate of the incidence of hyperplasia in animals surviving at least 582 days reveals that the occurrence of hyperplasia is increased in the low-dose (9/36) and high-dose (4/24) groups, but again there is no dose-response correlation (Table 2).

In evaluating the relevance of these results to human safety, the following factors should be considered: First, there is no difference in the incidence of pheochromocytomas in control and high-dose male mice surviving at least 582 days. The increased incidence of adrenal hyperplasia in treated male mice surviving 528 days was not accompanied by evidence of a significant dose-related increase in neoplasms of the adrenal medulla. In addition, there was no evidence of carcinogenicity in male and female F344 rats or B6C3F₁ female mice (NTP, 1992) and in a second carcinogenicity study in

Table 2. Summary of neoplastic and non-neoplastic effects in B6C3F₁ male mice^a

Lesion	Dose groups:		
	0 mg/kg/day	262 mg/kg/day	525 mg/kg/day
Pheochromocytoma incidence/total number mice (%)	2/48 (4.2%) $P = 0.472$	6/50 (12%) $P = 0.092$	1/50 (2.0%) $P = 0.592$
Pheochromocytoma incidence/total number mice surviving > 582 days (%)	2/43 (4.7%)	6/36 (17%)	1/24 (4.2%)
Adrenal medulla hyperplasia incidence/total number mice (%)	2/48 (4.2%) $P = 0.071$	9/50 ^b (18%) $P = 0.011$	4/50 (8.0%) $P = 0.191$
Adrenal medulla hyperplasia incidence/total number mice surviving more than 582 days (%)	2/43 (4.7%)	9/36 (25%)	4/24 (17%)

^aHistorical incidence for 2-year NTP corn oil gavage studies with vehicle control groups (mean \pm standard deviation): 18/582 (3.1% \pm 1.8%), range 0%–6%.

^bSignificantly different ($P < 0.05$) from the control group by logistic regression.

which six rats were administered a 2-mg dose of γ -butyrolactone by subcutaneous injection twice weekly for 104 weeks (Dickens and Jones, 1965).

Secondly, there is also no evidence to suggest that humans are subject to the type of adrenal medullary proliferative disease that is observed in laboratory rodent assays (Roe and Baer, 1985). In man, adrenal medullary proliferative disease is extremely rare (Symington, 1969). Furthermore, there is no evidence of any relationship between hyperadrenalism and the incidence of pheochromocytomas in humans.

Thirdly, based on the results of more than 50 genotoxicity studies (see Section IV, B.5 below), there is compelling evidence that γ -butyrolactone is not genotoxic. Fourthly, the ring-opened form of γ -butyrolactone is endogenous in humans as a metabolite of γ -amino butyrate (Roth *et al.*, 1980). Therefore, the results of the NTP bioassay are not relevant to the safety evaluation of low levels of intake of γ -butyrolactone from use as a flavour ingredient in humans.

5. Genetic toxicology

a. γ -Butyrolactone. No effects were reported in any of 16 mutagenicity studies of 4-hydroxybutanoic acid lactone using *Salmonella typhimurium* (Aeschbacher *et al.*, 1989; Baker and Bonin, 1981; Brooks and Dean, 1981; Garner *et al.*, 1981; Haworth *et al.*, 1983; Hubbard *et al.*, 1981; Ichinotsubo *et al.*, 1981; Katz *et al.*, 1981; Loquet *et al.*, 1981; MacDonald, 1981; Nagao and Takahashi, 1981; NTP, 1992; Rowland and Severn, 1981; Simon and Sheperd, 1981; Trueman, 1981; Venitt and Crofton-Sleigh, 1981) and one using *Escherichia coli* (Venitt and Crofton-Sleigh, 1981). Concentrations of up to 10,000 $\mu\text{g}/\text{plate}$ or up to 1.3 mmol (also 10 mg/ml) of the lactone were used in a variety of vehicles including DMSO, water, benzene and ethanol. Variations on the standard Ames assays performed in the above studies include preincubation, gene mutation induction, and S-9 metabolic activation. One study using up to 10,000 $\mu\text{g}/\text{plate}$ in DMSO with and without S-9 activation did show positive results; however, the result was not supported by a retest using newer strains of bacteria (Richold and Jones, 1981). A fluctuation test, also conducted with *S. typhimurium* with and without S-9 and rat hepatocytes, also showed no effects at doses up to 500 $\mu\text{g}/\text{ml}$ in DMSO (Hubbard *et al.*, 1981).

Of 36 applicable genotoxicity studies (two were considered not applicable due to false positive rates in controls), 30 reported no effects. The latter include sex-linked recessive lethal mutation tests (Foureman *et al.*, 1994; NTP, 1992), sister chromatid exchange and chromosomal aberration assays in Chinese hamster ovary cells and *Saccharomyces cerevisiae* (Kassinova *et al.*, 1981; NTP, 1992), unscheduled DNA synthesis *in vitro* using adult

human HeLa S3 cells with and without S-9 activation (Martin and McDermid, 1981), and human FL cell NAD content (Yingnian *et al.*, 1990).

Positive effects in six studies occurred at the highest dose levels or in non-standard assays for which interpretation is difficult. These results include: weak inhibition of *E. coli* DNA polymerase present only in a liquid suspension method with and without S-9 activation and in disc diffusion method without S-9 (Rosenkranz *et al.*, 1981); mitotic gene conversion induction in *S. cerevisiae* in which no effects were reported at 750 $\mu\text{g}/\text{ml}$ in EtOH, but some effects were seen at 500 $\mu\text{g}/\text{ml}$ in DMSO (Sharp and Parry, 1981); a positive result in the BHK-21 hamster kidney cell transformation assay with rat S-9 at 25–250 $\mu\text{g}/\text{ml}$, but with no effects at lower concentrations (Styles, 1981); a displacement of endoplasmic reticulum-polysomes in rat liver in DMSO at a concentration of 25 mg/litre (Fey *et al.*, 1981); lethal expression of gal genes under the control of "lambda prophage repressors" in DMSO with and without S-9 in a non-standard strain of *E. coli* (SA 500) at cytotoxic concentrations (Dambly *et al.*, 1981); and sperm mortality in mice following intraperitoneal injection of 1.0 ml/kg for 5 days, but no abnormal sperm at 0.1–1.0 ml/kg (Topham, 1981).

The FEMA Expert Panel reviewed genotoxicity data and concluded, on the basis of the weight of evidence, that γ -butyrolactone (4-hydroxybutanoic acid lactone) is not mutagenic and that isolated positive results performed in non-standard assays at high solution concentrations are not compelling evidence of genotoxic potential. The negative response in repeated *Salmonella* mutagenicity assays (Ashby and Tenant, 1991) supports the Panel's conclusion that exposure to 4-hydroxybutanoic acid lactone exhibits little potential for interaction with DNA.

b. Other aliphatic lactones (Nos 2–33). No mutagenic effects were reported in standard Ames tests using strains (TA98, TA100, TA102, TA1535 and TA1537) of *S. typhimurium* with δ -hexalactone (Kawachi *et al.*, 1981), γ -heptalactone (Heck *et al.*, 1989), γ -nonalactone (Heck *et al.*, 1989), γ -undecalactone (Fujita and Sasaki, 1987; Ishidate *et al.*, 1984; Yoo, 1986), ω -pentadecalactone (Aeschbacher *et al.*, 1989), and 1,4-dodec-6-enolactone (Watanabe and Kinoshita, 1990). γ -Heptalactone did not induce an increase in unscheduled DNA synthesis when concentrations of 3000 $\mu\text{g}/\text{ml}$ were incubated with rat hepatocytes (Heck *et al.*, 1989).

Aliphatic lactones exhibit equivocal results in cytogenetic assays [sister chromatid exchange (SCE) and chromosomal aberration (ABS) assays] and in mutation assays using cultured mouse lymphoma cells. In a SCE assay, δ -hexalactone does not induce sister chromatid exchanges in hamster lung fibroblast cells (Kawachi *et al.*, 1981). In an ABS assay, it induced an increase in aberrations in hamster lung fibroblast cells, but no induction was observed

in human embryo fibroblast cells or rat bone marrow cells (Kawachi *et al.*, 1981). γ -Undecalactone does not induce ABS when concentrations up to 500 mg/ml were incubated with hamster lung fibroblast cells (Ishidate *et al.*, 1984; Yoo, 1986). In the standard mouse lymphoma (MLA) assay, γ -nonalactone did not exhibit mutagenic activity with metabolic activation, but exhibited a positive mutagenic response at concentrations greater than 600 ml/ml without activation (Heck *et al.*, 1989).

The authors of the MLA study (Heck *et al.*, 1989) and others (Brusick, 1986) have emphasized that the positive results in the ABS and MLA assays may be artefacts resulting from changes in culture pH and osmolality. Treatment with high dose levels of substances with the potential to alter acidity or osmolality may induce a significant increase in mutant frequencies or aberrations in these assays. Often the results are inconsistent with the results of other genotoxicity assays (i.e. AMS and UDS) (Heck *et al.*, 1989).

The results of *rec*-assays with aliphatic lactones also are equivocal. δ -Hexalactone was negative in a *rec*-assay using *Bacillus subtilis* (Kawachi *et al.*, 1981). γ -Undecalactone (Kuroda, 1984; Yoo, 1986), δ -undecalactone (Kuroda *et al.*, 1984) and γ -nonalactone (Yoo, 1986) exhibited differences in growth inhibition zones between strains M45 (*rec*⁻) and H17 (*rec*⁺) of *B. subtilis* in the spore *rec*-assay. However, γ -undecalactone and δ -undecalactone failed to show any mutagenic activity using a similar test with the same bacterial strains (*B. subtilis* H17 and M45) (Oda *et al.*, 1978). 1,4-Dodec-6-enolactone was not mutagenic when inoculated with *E. coli* at concentrations of 500 μ g/plate (Watanabe and Kinoshita, 1990). γ -Undecalactone exhibited antimutagenic activity in a *rec*-assay using *E. coli* WP uvrA (*trp*⁻) pretreated with AF-2 or MNNG (Yoo, 1986).

The only *in vivo* genotoxicity study with an aliphatic lactone other than γ -butyrolactone was a single intraperitoneal injection of 2000 mg γ -undecalactone/kg to male ddY mice. No increase in micronucleated polychromatic erythrocytes in B6C3F₁ mouse bone marrow cells was observed (Hayashi *et al.*, 1988).

Based on the results of the battery [i.e. AMS(-), UDS (-), SCE(-), ABS(+/-) and MLA (+/-)] of *in vitro* genotoxicity tests and the evidence that neither γ -butyrolactone nor γ -undecalactone were genotoxic *in vivo* in the mouse micronucleus assay or sex-linked lethal assay, it is concluded that the group of aliphatic lactones formed from straight- and branched-chain aliphatic hydroxycarboxylic acids is not genotoxic.

6. Lactones fused to alicyclic ring systems (Nos 36-39)

The alicyclic lactone formed from the enol form of 9-carboxymenthone dehydromenthofurolactone

(No. 38) has been added to the diet of rats at levels providing 1.0, 10.0 and 100.0 mg/kg daily for 13 weeks (Voss *et al.*, 1985) (see Table B6). Slight to mild hyperkeratosis and epithelial thickening of the oesophageal mucosa and squamous forestomach were reported in mid- and high-dose animals. Increased relative liver weights were reported in the mid- and high-dose groups. As absolute liver weights were unchanged, the increased relative organ weights were attributed to lower body weight gains associated with decreased palatability of the test diet. The 1.0 mg/kg no-effect level is greater than 1000 times the anticipated daily *per capita* intake ("eaters only") of 0.7 mg/kg from use of dehydromenthofurolactone as a flavour ingredient.

7. Lactones fused to aromatic ring systems (Nos 40-44)

Subchronic and chronic oral studies are available for 6-methylcoumarin and dihydrocoumarin, and a 90-day subchronic study has been performed with the phthalide derivative 3-propylidenephthalide (see Table B4). No adverse effects were reported when 3-propylidenephthalide was added to the basal diet of rats providing an average daily intake of 5.4 mg/kg for males and 6.5 mg/kg for females for 90 days (Posternak *et al.*, 1969). The 5.4 or 6.5 mg/kg/day dose level that produced no effects in rats is greater than 100,000 times the daily *per capita* intake ("eaters only") of 0.05 μ g/kg from use of 3-propylidenephthalide as a flavour ingredient.

No adverse effects were reported when rats were maintained on diets containing 6-methylcoumarin (No. 42) at levels up to 10,000 ppm for 14 weeks (Hagan *et al.*, 1967). The dietary level of 10,000 ppm is calculated to provide an average daily intake of 500 mg/kg (FDA, 1993). For 2 years, rats were maintained on diets containing 6-methylcoumarin (Hagan *et al.*, 1967) at levels calculated to provide an average daily intake of up to 750 mg/kg (FDA, 1993). Depression in growth rates was noted in males provided 375 mg/kg/day. At 750 mg/kg/day, growth depression was severe in males and moderate in females. Hepatic effects at 750 mg/kg/day included fatty metamorphosis, slight bile duct proliferation and focal telangiectasis. No adverse effects were observed at intake levels up to 175 mg/kg/day.

6-Methylcoumarin was administered to dogs by capsule at a daily dose level of 150 mg/kg, 6 days per week for 39 days. Moderate to severe hepatitis and atrophy of skeletal muscle was reported (Hagan *et al.*, 1967). No adverse effects were observed when dogs were given 50 mg 6-methylcoumarin/kg by capsule, 6 days/week for 2 years (Hagan *et al.*, 1967).

The mechanism of hepatotoxicity of coumarin and related coumarin derivatives, including 6-methylcoumarin, has been studied in rats (Lake *et al.*, 1994b). For 13 weeks rats were fed diets containing 0.5 and 0.75% coumarin or 0.82% 6-

methylcoumarin (equimolar to the 0.75% dietary level of coumarin). Dose levels of 6-methylcoumarin are calculated (FDA, 1993) to provide an average daily intake of 410 mg/kg. Although relative liver weights and γ -glutamyl transferase were increased for all treated groups, only coumarin-treated animals exhibited increased levels of plasma aminotransferase. Histopathological examination of coumarin-treated animals revealed vacuolation of centrilobular hepatocytes, bile duct hyperplasia and cholangiofibrosis, particularly in rats fed the 0.75% diet. No increase in plasma aminotransaminase levels and no bile duct hyperplasia or cholangiofibrosis were observed in animals maintained on the 6-methylcoumarin diet, and only a slight vacuolation of hepatocytes were observed in a minority of animals. 6-Methylcoumarin treatment increased mixed function oxidase activity (i.e. 7-ethoxycoumarin *O*-deethylase activity), which supports other reports that 6-methylcoumarin can induce hepatic cytochrome *P*-450 activity in the rat (Feuer, 1974). 6-Methylcoumarin did not markedly effect the activities of carnitine acetyltransferase and palmitoyl-CoA oxidation, indicating that 6-methylcoumarin is unlikely to be a rodent liver peroxisome proliferator (Lake and Lewis, 1993; Lock *et al.*, 1989).

The 175 mg/kg/day intake level in the 2-year rat study and the 50 mg/kg/day dose level in the 2-year dog study that produced no adverse effects are at least 50,000 times the daily *per capita* intake ("eaters only") of 1 μ g/kg from use of 6-methylcoumarin as a flavour ingredient.

No adverse effects were reported when rats were administered up to 10,000 ppm dihydrocoumarin (No. 40) in the diet for 14 weeks (Hagan *et al.*, 1967). This dietary level is calculated to provide an average daily intake of 500 mg/kg (FDA, 1993). No adverse effects were reported when dihydrocoumarin was added to the diet of rats at a level providing 110 mg/kg/day for 12 weeks (Trubeck Labs, 1957) and to dogs at levels of 50 and 150 mg/kg/day for 2 years (Hagan *et al.*, 1967).

Groups of male and female rats were administered dihydrocoumarin in corn oil by gavage 5 days per week for 13 weeks providing dose levels of 75, 150, 300, 600 or 1200 mg/kg/day (NTP, 1993). No adverse effects were observed at the 75 and 150 mg/kg/day levels. Increased absolute and relative liver and kidney weights were reported in both sexes at the 600 mg/kg/day and 1200 mg/kg/day dose levels. Hepatocellular hypertrophy was reported at the three highest dose levels. Male and female rats receiving 600 mg/kg/day for up to 2 years exhibited elevated alkaline phosphatase and alanine aminotransferase activity. Rats receiving 300 mg/kg/day or greater for 13 weeks, and 300 or 600 mg/kg/day for periods up to 2 years exhibited a mild anticoagulant effect. A companion gavage study in mice given 100, 200, 400, 800 and 1600 mg/kg/day resulted in increased absolute liver weights in both

sexes and increased relative kidney weights in males only at the 1600 mg/kg/day level. Dihydrocoumarin administration to mice at dose levels less than 800 mg/kg/day for up to 2 years produced no change in hepatic enzyme activities and resulted in no treatment-related lesions.

A recent subchronic study in rats demonstrates the different hepatotoxic potential of coumarin and dihydrocoumarin (Lake *et al.*, 1994). For 13 weeks rats were fed diets containing 0.5 and 0.75% coumarin or 0.76% dihydrocoumarin (equimolar to the 0.75% dietary level of coumarin). Although relative liver weights were increased for all treated groups, histopathological examination of dihydrocoumarin-treated animals revealed no abnormalities. Coumarin-treated animals exhibited increased plasma amino acid transferase levels which were accompanied by vacuolation of centrilobular hepatocytes, bile duct hyperplasia and cholangiofibrosis, particularly in rats fed the 0.75% diet. Dihydrocoumarin did not markedly affect the activities of carnitine acetyltransferase and palmitoyl-CoA oxidation, indicating that dihydrocoumarin is unlikely to be a rodent liver peroxisome proliferator (Lake and Lewis, 1993; Lock *et al.*, 1989). The dietary level of 0.76% dihydrocoumarin that produced no significant effects is calculated (FDA, 1993) to provide an average daily intake of 380 mg/kg. The dose levels of 150 mg/kg/day by gavage and 380 mg/kg/day in the diet that produced no adverse effects are greater than 10,000 times the daily *per capita* intake ("eaters only") of 12 mg/kg* from use of dihydrocoumarin as a flavour ingredient.

8. Results of the 2-year NTP bioassay with 3,4-dihydrocoumarin

a. Effects on growth, survival, clinical findings, haematology and clinical chemistry. A chronic study of dihydrocoumarin was conducted by the National Toxicology Program (NTP, 1993a). The standard NTP protocol was used with F344/N rats and B6C3F₁ mice of both sexes. Rats and mice received dihydrocoumarin in corn oil by gavage 5 days per week for 103 weeks, providing dose levels of 0, 150, 300 or 600 mg/kg to rats and 0, 200, 400 or 800 mg/kg to mice. In a dose-related manner, decreased survival rates were reported only in male rats at all dose levels with the majority of deaths occurring after week 92. The decreased survival was attributed to a progressive degenerative nephropathy leading to renal failure. Typically, the severity of nephropathy increased with dose level. The mean body weight gain of high-dose males was significantly lower (5% to 10%) than that of controls.

In a related stop-exposure evaluation, a group of 40 male rats received 600 mg/kg body weight dihydrocoumarin by gavage for 9 months. 20 rats were sacrificed after 9 months and the remaining rats (20), which were designated the 9-month stop-exposure group, received only the corn oil vehicle

until death or the end of the study. A second group of male rats (30) received 600 mg/kg body weight dihydrocoumarin by gavage. 10 of these rats were sacrificed at 15 months and the remaining rats (20), which were designated the 15-month stop-exposure group, received only the corn oil vehicle until death or the end of the study. Groups of 20 and 10 control rats receiving only the corn oil vehicle by gavage were sacrificed at 9 and 15 months, respectively. To determine the progression or regression of chemically-related lesions during the recovery period, neoplastic and non-neoplastic lesions in the 9- and 15-month stop-exposure groups were compared with those of the groups sacrificed at 9 and 15 months, respectively.

The incidence of nephropathy in the stop-exposure groups was not statistically different from that of the control group or groups sacrificed at 9 or 15 months, but the nephropathy was more severe. The observation that the process is irreversible and that nephropathy appears in all groups of control and treated male rats supports the conclusion that it is a progressive degenerative disease associated with the ageing process, especially in male F344/N rats. This background level of kidney disease may make the male F344/N rat particularly susceptible to any chemically-induced nephrotoxicity. The sex- and species-specific nature of the nephrotoxic effect was confirmed by the observations that female rats and mice of both sexes exhibited no significant change in survival rates, mean body weight changes, and no clinical findings of renal toxicity related to the administration of dihydrocoumarin.

Haematology and clinical chemistry performed at the 15-month interim evaluation revealed statistically significant increased serum levels of alanine aminotransferase (ALT), alkaline phosphatase (ALP), sorbitol dehydrogenase or γ -glutamyl transferase (GGT) in male rats at 300 and 600 mg/kg. Increased ALP and GGT were reported for female rats at 600 mg/kg. Only the ALT level (approx. four times greater than control values) in male rats at 600 mg/kg may be considered to be biologically significant for this species. Although significant changes in the activity of this enzyme are normally associated with altered liver function, the increase in ALT was not accompanied by evidence of histopathology. There was no significant difference in haematology or clinical chemistry parameters for mice at any dose level. Administration of 3,4-dihydrocoumarin in the 2-year chronic study did not produce coumarin like-induced hepatotoxicity in either rats or mice.

b. Pathological findings

(1) Renal neoplasms in male rats: Nephropathy was manifest in both sexes of control and dosed rats, but was more severe in animals that received the test compound. The incidence of nephropathy

was greater in male rats than female rats, indicating a greater susceptibility of males to chronic nephropathy.

Microscopic examination of combined single and step sections of the kidneys of male rats revealed a statistically significant, dose-related increase in renal tubule hyperplasia (control, 1/50; 150 mg/kg, 5/48; 300 mg/kg, 6/47; 600 mg/kg, 8/50). The incidence of renal tubule adenomas in the treated groups of male rats was not significantly different ($P < 0.05$) than the control group (control, 1/50; 150 mg/kg, 1/48; 300 mg/kg, 3/47; 600 mg/kg, 6/50), but the total incidence of renal tubule adenomas in all groups of treated male rats (10/145) and in the high-dose group (6/50) exceeds the range in NTP historical controls (8/1019) (Table 3). Renal transitional cell carcinomas were reported in two male rats succumbing early in the study (i.e. days 444 and 528) at the 600 mg/kg dose level. There was no evidence of transitional cell carcinomas in the majority (86%) of males surviving longer than 528 days. The incidence of renal tubule hyperplasia and renal tubule adenomas in stop-exposure groups and 2-year treatment group [600 mg/kg dose level: 9 months, 1/2 (hyperplasia/adenomas); 15 months, 4/2; 24 months, 8/6] increased with the duration of treatment. However, analysis of step sections revealed no additional evidence of treatment-related response of the renal transitional cells. There was no increased incidence of malignant renal tubule neoplasms in any group of treated male or female rats.

(2) Renal neoplasms in female rats and male and female mice: The incidence of renal nephropathy in control and treated female rats was significantly less than in males. No significant differences in the incidence of renal tubule hyperplasia or renal tubule adenoma was observed between control and treated groups of female rats. The incidence of renal focal hyperplasia and adenomas in treated and control groups of male mice were not significantly different, and the incidence of renal tubule neoplasms was low and not dose related (controls 0/50; 200 mg/kg, 1/51; 400 mg/kg, 2/51; 800 mg/kg, 1/49) (Table 3). There was no incidence of renal tubule hyperplasia or renal tubule neoplasms in female mice.

The NTP report concluded the following: "*Under the conditions of these 2-year gavage studies, there was some evidence of carcinogenicity of 3,4-dihydrocoumarin in male F344 rats based on the increased incidence of renal tubule adenomas and focal hyperplasia. The transitional cell carcinomas in two 600 mg/kg males may also have been chemical related. There was no evidence of carcinogenic activity of 3,4-dihydrocoumarin in female F344 rats receiving 150, 300 or 600 mg/kg. There was no evidence of carcinogenic activity of 3,4-dihydrocoumarin in male B6C3F₁ mice receiving 200, 400 or 800 mg/kg.*"

Chronic renal nephropathy and an increased incidence of focal hyperplasia and renal tubule neo-

Table 3. Incidences of renal neoplasms associated with administration of dihydrocoumarin to rats and mice by gavage for 2 years

	Control	150 mg/kg	300 mg/kg	600 mg/kg
1. Male rats

*Significantly different ($P < 0.05$) from control group by Fisher's exact test (15 month interim), logistics regression test (2-year study) or Mann-Whitney U test.

**Significantly different ($P < 0.01$) from the control group.

^aCombined single and step sections.

plasms were reported when dihydrocoumarin was administered to male rats by corn oil gavage for 2 years. Although treated female rats also exhibited increased nephropathy at the two highest dose levels, they did not experience a significant increase in either renal tubule hyperplasia or renal tubule neoplasms. The incidence of renal tubule hyperplasia and neoplasms in male mice were not statistically significant and not dose related. Female mice did not exhibit any renal neoplasms. Additionally, no renal histopathology was observed in dietary studies providing similar dose levels of dihydrocoumarin to rats or dogs for periods up to 2 years (Hagan *et al.*, 1967; Trubeck Labs, 1957). Therefore, the renal hyperplastic and neoplastic effects are sex and species specific and occur only at high chronic levels of exposure.

The metabolic fate of dihydrocoumarin at high dose levels may confound the interpretation of the renal effects in male rats. If dihydrocoumarin metabolizes to high endogenous levels of *o*-hydroxybenzoic acid (i.e. salicylic acid), the metabolite may produce a unique renal toxicity observed with chronic exposure to analgesics. The renal toxicity is characterized by renal medullary and papillary necrosis (Tarloff and Goldstein, 1995). The non-neoplastic lesions of the kidney observed for chronic intake of high dose levels of dihydrocoumarin and analgesics such as acetaminophen (NTP, 1993b) in 2-year bioassays show marked similarities.

The male rat kidney has been shown to be a unique target organ for the carcinogenic effects of a variety of chemical substances (Burdock *et al.*, 1990; EPA, 1991). The FEMA Expert Panel concludes that the renal effects of dihydrocoumarin in the male rat are, indeed, a species- and sex specific phenomena, and in all probability, reflect the sensitivity of the male rat kidney to chronic progressive nephropathy, focal hyperplasia, and specific tumorigenic responses. The observed histopathology suggests that the hyperplastic and neoplastic effects

are not associated with the accumulation of $\alpha_2\mu$ -globulin in proximal convoluted renal tubules. The relationship of the 600 mg/kg dose level of dihydrocoumarin to the report of transitional cell carcinomas in two male rats is unclear. It was reported that longer-lived males showed no evidence of renal transitional cell changes at any dose level.

(3) Forestomach effects in rats: A significant increase in the incidence of forestomach ulcers in male rats was reported at the end of the study, but not at the 15-month interim evaluation. An increased incidence of ulcers, squamous hyperplasia and chronic inflammation occurred at all dose levels, but the effects were not related to dose. Female rats exhibited no significant forestomach effects. Two neoplasms (a squamous cell papilloma and carcinoma) reported at the 600 mg/kg dose level were not attributed to chemical administration.

(4) Hepatocellular neoplasms in mice: Neoplastic and non-neoplastic lesions associated with administration of dihydrocoumarin to mice developed principally in the liver (Table 4). There was a significant increase in the incidence of hepatocellular adenomas (control, 10/51; 200 mg/kg, 20/50; 400 mg/kg, 22/50; 800 mg/kg, 20/52) and combined hepatocellular adenomas and carcinomas (control, 13/51; 200 mg/kg, 21/50; 400 mg/kg, 25/50; 800 mg/kg, 24/52) in female mice compared with that of the control group, but the incidence of neoplasms was not dose related (Table 4). The amount of time required for onset of neoplasms in the high-dose group was shorter than that for lower-dose groups. No increased incidence of malignant neoplasms of the liver was observed in treated female mice.

The incidence of hepatocellular neoplasms in treated and control male mice was greater than in treated and control female mice, indicating the increased susceptibility of the male mouse liver to neoplastic changes. However, the incidence of hepa-

^aHistorical incidence for 2-year corn oil gavage studies with vehicle control groups (mean \pm SD): 370/901 (41.1 \pm 15.5%); range 14% to 72%.

^bHistorical incidence: 129/898 (14.4% \pm 8.1%); range 2% to 34%.

tocellular adenomas (control, 29/50; 200 mg/kg, 23/51; 400 mg/kg, 36/51; 800 mg/kg, 31/50) and carcinomas (control, 11/50; 200 mg/kg, 11/51; 400 mg/kg, 11/51; 800 mg/kg, 6/50) in treated male mice was not significantly different from that of the control group. There was no evidence of an increased incidence of malignant neoplasms of the liver in either male or female mice.

The NTP report concluded the following: "There was no evidence of carcinogenic activity of 3,4-dihydrocoumarin in male B6C3F₁ mice receiving 200, 400, or 800 mg/kg. There was some evidence of carcinogenic activity in female B6C3F₁ mice based on increased incidences of hepatocellular adenoma, and hepatocellular adenoma and carcinoma (combined)."

The primary neoplastic effects observed in mice in the NTP study were associated with the liver. The high incidence of hepatocellular adenomas and carcinomas in both control and treated groups of male and female mice demonstrate the sensitivity of the B6C3F₁ mouse liver to neoplastic responses. The high incidence of hepatocellular adenoma was not significantly different between treated and control groups of male mice (control, 29/50; 200 mg/kg, 23/51; 400 mg/kg, 36/51; 800 mg/kg, 31/50). The observation that the incidence of adenomas in control males was greater than in any group of treated females demonstrates the increased sensitivity of the male mouse liver. The incidence of hepatocellular adenomas in all groups of treated female mice were significantly greater than the control group, but the response was not dose related (control, 10/51; 200 mg/kg, 20/50; 400 mg/kg, 22/50; 800 mg/kg, 20/52). The incidence of hepatocellular carcinomas was not significantly different between treated and control groups of male mice (control, 11/50; 200 mg/kg, 11/51; 400 mg/kg, 11/51; 800 mg/kg, 6/50), but again the incidence of carcinomas in control males was greater than in any group of treated females. The lower incidence of hepatocellular carcinomas in groups of treated female mice was not significantly different from that of the control group (3/51, 2/50, 4/50, 6/52). These neoplastic responses are consistent with the historically high levels of background hepatocellular neoplasms in B6C3F₁ mice (Maronpot and Boorman, 1982; Maronpot *et al.*, 1986).

The FEMA Expert Panel considers that the observations of hepatic neoplasms in the NTP mouse bioassay are not relevant to the safety of dihydrocoumarin in humans at low levels of intake from use as a flavour ingredient. This conclusion is based on the high incidence of spontaneous hepatocellular neoplasms (adenomas and carcinomas) in the strain of mice studied, the absence of consistent dose-response data, the lack of hepatocellular neoplastic effects in rats, and the relatively high dose levels administered as compared with intake levels from use as a flavour ingredient. Additionally, based on the metabolism of structurally related substances, humans may metabolize low intake levels of dihydrocoumarin via a different principal pathway (i.e. β -oxidation and cleavage) than the pathway (i.e. β -hydroxylation) used by rodents (Samuelson *et al.*, 1986) at high intake levels.

9. Genetic toxicology of 3,4-dihydrocoumarin

Dihydrocoumarin was not mutagenic for *S. typhimurium* strains (TA98, TA100, TA1535 and TA1537) with or without S-9 metabolic activation (Haworth *et al.*, 1983; Heck *et al.*, 1989; NTP, 1993; Prival *et al.*, 1982). Dihydrocoumarin concentrations of 1400 mg/ml were reported to be mutagenic for mouse lymphoma L5178TK + /- only in the presence of S-9 activation (Heck *et al.*, 1989).

In a cytogenetic test, effective dose levels of 50 to 300 mg dihydrocoumarin/ml induced a dose-related increase in sister chromatid exchanges (SCE) in Chinese hamster ovary (CHO) cells in the absence of S-9. In the presence of S-9, an increase in SCE was observed only at the highest concentrations (1600 and 2000 mg/ml) in each of two tests. Dihydrocoumarin did not induce chromosomal aberrations in CHO at concentrations up to 500 mg/ml without S-9 and up to 1600 mg/ml with S-9 (NTP, 1993a).

No increase in the frequency of micronucleated erythrocytes was reported in peripheral blood samples obtained from male and female mice after 13 weeks at dose levels up to 800 mg/kg (NTP, 1993a).

The FEMA Expert Panel reviewed genotoxicity data and concluded, on the basis of the weight of evidence, that dihydrocoumarin was not mutagenic

and that the isolated positive results from an SCE-CHO assay performed at high solution concentrations of dihydrocoumarin were not compelling evidence of a genotoxic potential. The negative response in the *Salmonella* mutagenicity assay (Ashby and Tenant, 1991) supports the Panel's conclusion that exposure to dihydrocoumarin exhibits little potential for interaction with DNA.

35. 4,5-Dimethyl-3-hydroxy-2,5-dihydrofuran-2-one	3634	0.2	0.5	0.002	+	NR

NR = not reported NA = not applicable

¹Intake ($\mu\text{g/kg body weight/day}$) calculated as follows: $[(\text{annual volume, kg}) \times (1 \times 10^6 \mu\text{g/kg}) / (\text{population} \times 0.6 \times 60 \text{ kg body weight} \times 365 \text{ days})]$, where population (10%, "eaters only") = 24×10^6 , 0.6 represents the assumption that only 60% of the flavour volume was reported in the survey (NAS, 1987).

²Substances occurring in more than 10, six to 10, and one to five foods are given the respective designations, +, +, +, +, + and + as reported in CIVO, 1994.

³Consumption ratios were calculated using the method by Stofberg and Kirschman, 1985 and data by Stofberg and Grundschober, 1987.

NR = none reported NA = not applicable, since studies on the parent substance have been reported

¹A “+” indicates that metabolic data has been reported for the specific flavour ingredient. A “—” indicates that metabolic data for the specific flavour ingredient has not been reported and metabolic fate is presumed based on data from structurally related substances.

²The no-observed-adverse-effect level (NOAEL) is reported for oral administration of the substance either in food or in the drinking water, unless noted. Abbreviations used for “Duration”:

d = days; m = month(s); wk = week(s); yr = year(s).

Contents

1. Introduction	1
2. General considerations	1
2.1 Modification of the agenda	2
2.2 Principles governing the toxicological evaluation of compounds on the agenda	2
2.2.1 Procedure for the Safety Evaluation of Flavouring Agents	3
2.2.2 Role of the Committee in the risk analysis process of the Codex Alimentarius Commission	6
2.3 Principles governing the establishment and revision of specifications	6
2.3.1 Significance of identity and purity requirements	6
2.3.2 Limits for arsenic, lead and other heavy metals	7
2.3.3 Analytical methods	7
2.3.4 Enzymes derived from genetically modified organisms	8
2.3.5 Flavouring agents	8
2.4 Principles governing intake assessments of food additives and contaminants	9
2.4.1 Methods for assessing dietary intake	9
2.4.2 Assessment of dietary intake of specific additives	10
3. Specific food additives and food ingredients	11
3.1 Antioxidant: <i>tert</i> -butylhydroquinone (TBHQ)	11
3.2 Emulsifiers	14
3.2.1 Microcrystalline cellulose	14
3.2.2 Sucrose esters of fatty acids and sucroglycerides	16
3.3 Enzyme preparations	17
3.3.1 α -Acetolactate decarboxylase	17
3.3.2 Maltogenic amylase	18
3.4 Flavouring agent: <i>trans</i> -anethole	20
3.5 Glazing agent: hydrogenated poly-1-decene	21
3.6 Sweetening agent: maltitol syrup	21
3.7 Miscellaneous substance: salatrim (short- and long-chain acyltriglyceride molecules)	23
4. Substances evaluated using the Procedure for the Safety Evaluation of Flavouring Agents	25
4.1 Allyl-2-furoate	28
4.2 Saturated aliphatic acyclic linear primary alcohols, aldehydes and acids	29
4.3 Saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids	37
4.4 Aliphatic lactones	42
4.5 Esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids	52
4.6 Esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids	56

4.7 Esters derived from branched-chain terpenoid alcohols and aliphatic acyclic carboxylic acids	64
4.8 Specifications for flavouring agents	69
5. Contaminants: aflatoxins	69
6. Revision of certain specifications	77
7. Recommendations	80

Monographs containing summaries of relevant data and toxicological evaluations are available from WHO under the title:

Safety evaluation of certain food additives and contaminants. WHO Food Additives Series, No. 40, 1998.

Specifications are issued separately by FAO under the title:

Compendium of food additive specifications, Addendum 5. FAO Food and Nutrition Paper, No. 52, Add. 5, 1997.

INTERNATIONAL PROGRAMME ON CHEMICAL SAFETY

The preparatory work for toxicological evaluations of food additives and contaminants by the Joint FAO/WHO Expert Committee on Food Additives (JECFA) is actively supported by certain of the Member States that contribute to the work of the International Programme on Chemical Safety (IPCS).

The International Programme on Chemical Safety (IPCS) is a joint venture of the United Nations Environment Programme, the International Labour Organisation, and the World Health Organization. One of the main objectives of the IPCS is to carry out and disseminate evaluations of the effects of chemicals on human health and the quality of the environment.

1. Introduction

The Joint FAO/WHO Expert Committee on Food Additives met in Rome from 17 to 26 June 1997. The meeting was opened by Dr H. de Haen, Assistant Director-General, FAO, on behalf of the Directors-General of the Food and Agriculture Organization of the United Nations and the World Health Organization. Dr de Haen emphasized the importance of the work of the Committee and its impact on international trade and stressed the necessity for transparency in its deliberations. Dr de Haen highlighted the significance of accurate, comprehensive and concise reporting of the proceedings and deliberations of the Committee's meetings. He also stated that the scientific committees that advise the Codex Alimentarius Commission must have adequate expertise and experience to enable them to perform accurate and scientifically sound evaluations. FAO and WHO make every effort to ensure that the process for the selection of Committee members is open and transparent, and that this process results in the selection of highly qualified scientists in the fields of competence needed to make important decisions that affect the safety of the world's food supply.

2. General considerations

As a result of the recommendations of the first Joint FAO/WHO Conference on Food Additives, held in September 1955 (*1*), there have been 48 previous meetings of the Expert Committee (Annex 1). The present meeting was convened on the basis of the recommendation made at the forty-sixth meeting (Annex 1, reference *122*).

The tasks before the Committee were:

- to elaborate further principles for evaluating the safety of food additives and contaminants (section 2);
- to undertake toxicological evaluations of certain food additives, food ingredients, flavouring agents and contaminants (sections 3, 4 and 5 and Annex 2);
- to review and prepare specifications for selected food additives and flavouring agents (sections 3, 4 and 6 and Annex 2);
- to assess the risks associated with aflatoxin contamination (section 5); and
- to consider approaches to evaluate the intake of food additives in the light of the recommendations of the Twenty-ninth Session of the Codex Committee on Food Additives and Contaminants (2) (section 2.4.2).

2.1 Modification of the agenda

The flavouring agents isoamyl alcohol, isoamyl formate and isoamyl acetate were removed from the agenda for toxicological evaluation because they had been evaluated at the forty-sixth meeting of the Committee (Annex 1, reference 122). The flavouring agent geranyl 2-ethylbutanoate (*trans*-3,7-dimethyl-2,6-octadien-1-yl 2-ethylbutanoate) was on the agenda under the esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids; however, it was evaluated with the esters derived from branched-chain terpenoid alcohols and aliphatic acyclic carboxylic acids. The flavouring agent 4-hydroxy-3-methyloctanoic acid γ -lactone was added for toxicological evaluation under the aliphatic lactones.

Sixty flavouring agents included on the agenda under the saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids and the aliphatic lactones were not considered for specifications at the present meeting. The specifications for these substances will be reviewed at a future meeting of the Committee at which food additives and contaminants are considered.

The Twenty-ninth Session of the Codex Committee on Food Additives and Contaminants (2) reviewed the specifications of identity and purity of selected food additives that had been prepared at the forty-sixth meeting of the Expert Committee (Annex 1, reference 122). The Codex Committee referred back to the Expert Committee the specifications of nine compounds: citric acid, propylene glycol, allyl cyclohexane propionate (2-propenyl cyclohexane propanoate), ethyl nonanoate, ethyl octanoate, isoamyl acetate (3-methylbutyl acetate), isoamyl butyrate (3-methylbutyl butanoate), isoamyl isobutyrate (3-methylbutyl 2-methylpropanoate) and isoamyl isovalerate (3-methylbutyl 3-methylbutanoate); these were added to the agenda of the present meeting.

2.2 Principles governing the toxicological evaluation of compounds on the agenda

In making recommendations on the safety of food additives, food ingredients, flavouring agents and contaminants, the Committee took into consideration the principles established and contained in Environmental Health Criteria, No. 70, *Principles for the safety assessment of food additives and contaminants in food* (Annex 1, reference 76), as well as the principles elaborated subsequently at meetings of the Committee (Annex 1, references 77, 83, 88, 94, 101, 107, 116 and 122), including the present one. Environmental Health Criteria, No. 70 (Annex 1, reference 76) embraces the major observations, comments

and recommendations on the safety assessment of food additives and contaminants contained, up to the time of its publication, in the reports of the Committee and other associated bodies. The Committee noted that the document reaffirms the validity of recommendations that are still appropriate, and points out the problems associated with those that are no longer valid in the light of modern technical advances.

2.2.1 ***Procedure for the Safety Evaluation of Flavouring Agents***

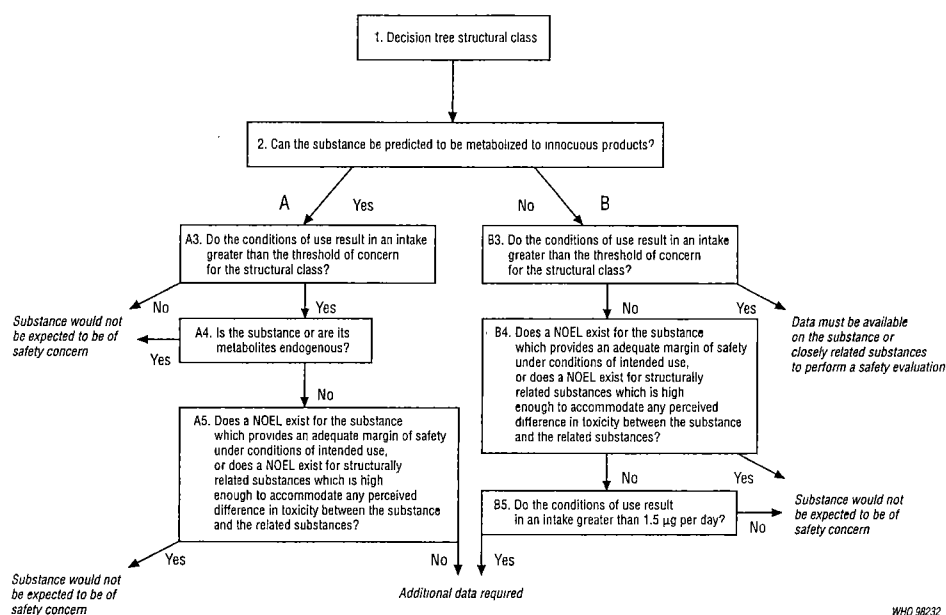

At its forty-sixth meeting (Annex 1, reference 116), the Committee evaluated three groups of flavouring agents using a procedure based on that reviewed at its forty-fourth meeting (Annex 1, reference 122). At the forty-sixth meeting, the Committee did not fully discuss the application of the last step on the right-hand side of the Procedure (“Do the conditions of use result in an intake greater than 1.5 µg per day?”) to flavouring agents and this step was not considered. At that time, the Committee recommended that this step be considered at a future meeting at which food additives and contaminants were evaluated.

At its present meeting, the Committee considered the numbering of the various steps in the Procedure for the Safety Evaluation of Flavouring Agents. Concern was expressed about the numbering system used in the Procedure at the forty-sixth meeting, which implied that the two sides of the Procedure were parallel. To avoid this confusion, the Committee decided to prefix the steps on the left- and right-hand sides of the Procedure with the letters “A” and “B” respectively.

At its present meeting, the Committee also considered a paper that will be published in the WHO Food Additives Series (3) that provided further information relating to the derivation of the value of 1.5 µg per person per day. The Committee noted that this value was based on a risk analysis of known carcinogens which involved several conservative assumptions. The use of this value was supported by additional information on developmental toxicity, neurotoxicity and immunotoxicity. In the judgement of the Committee, flavouring substances for which insufficient data are available for them to be evaluated using earlier steps in the Procedure, but for which the intake would not exceed 1.5 µg per person per day would not be expected to present a safety concern. The Committee recommended that the Procedure for the Safety Evaluation of Flavouring Agents used at the forty-sixth meeting be amended to include the last step on the right-hand side of the original procedure (“Do the conditions of use result in an intake greater than 1.5 µg per day?”) (Fig. 1). The Committee

Figure 1

Procedure for the Safety Evaluation of Flavouring Agents adopted by the Committee at its present meeting

recognized that flavouring agents with unresolved toxicity problems could be evaluated by steps B3, B4 and B5 of the Procedure, but reaffirmed its view, expressed at the forty-sixth meeting, that as with any scheme, its application calls for judgement, and it should not replace expert opinion; the Committee therefore reserved the right to use alternative approaches when data on specific flavouring agents warranted such action.

During its present meeting, the Committee used the Procedure for the Safety Evaluation of Flavouring Agents given in Fig. 1.

In applying the Procedure at the present meeting, a number of general issues were raised.

Consideration of flavouring agents as groups

The flavouring agents were evaluated by the Committee in groups of structurally and/or metabolically related substances. Systematic changes in structure are the basis for understanding the effect of structure on the chemical and biological properties of a substance (Annex 1, reference 117, Annex 5). When the Procedure is being used, the evaluation of flavouring agents in groups facilitates the consideration of common pathways of metabolism which apply to

members of a group. For substances which share common metabolites, consideration should be given to the total intake from all related substances. The total intake of such related flavouring agents, either from within the same group or across groups, should be evaluated where assessment of the intake data and toxicological profile warrant a combined appraisal. Total intakes should be considered for substances which produce the same potentially toxic metabolite (for example the esters of allyl alcohol considered at the forty-sixth meeting of the Committee (Annex 1, reference 122)). The Committee concluded that flavouring agents which produce metabolites that are innocuous and endogenous would not be of safety concern, providing that the total intake from all related substances was judged not to give rise to perturbations outside the normal physiological range. Evaluations of such theoretical combined intakes should also take into account, where possible, the likelihood of the different flavouring agents being consumed together.

Natural occurrence

Some substances used as flavouring agents also occur as natural constituents of food; the influence of natural occurrence on the application of the Procedure was considered at the forty-fourth meeting of the Committee (Annex 1, reference 117, Annex 5). Intakes from use as flavouring agents should be considered relative to the intakes from natural sources. This is a complex issue and interpretation of data on natural occurrence is dependent on:

- the nature of the flavouring substance and its structural class (step 1);
- the natural source of the substance;
- the intake from natural sources; and
- the proportion of the total intake accounted for by its use as a flavouring agent.

As a consequence the intake of such naturally occurring substances should be considered on a case-by-case basis.

Data on intakes of flavouring agents

The only estimates of intake of flavouring agents available to the Committee were derived from surveys in Europe and the USA. The Committee would welcome additional information on intakes of flavouring agents from other geographical regions. The Committee noted that the evaluations performed to date using the Procedure have been based on intake estimates available at the meeting at which the flavouring agents were considered and that changes in intake might warrant re-evaluation of a flavouring agent. The Committee

recommended that information on intakes be updated periodically to ensure the validity of the safety evaluations, particularly for flavouring agents for which the annual volume of production is variable.

The Committee considered that the estimation of intakes based on production data is a practical and realistic approach. Further consideration of intake should be given to flavouring agents for which there are high reported levels of use in some foods or beverages, but low intakes when calculated from production data. This would be particularly important for flavouring agents with intakes calculated to be only slightly below one of the threshold criteria in the evaluation process (i.e. steps A3, B3 or B5). However, the Committee recognized that estimation of intakes of flavouring agents based on reported levels of use would require detailed information on the specific products in which the flavouring agent is used, the actual levels of use and the intake of the individual food products containing the flavouring agent by consumers of both average and above average quantities of these foods.

2.2.2 *Role of the Committee in the risk analysis process of the Codex Alimentarius Commission*

The Committee welcomed the acknowledgement by the Codex Alimentarius Commission of the continuing need for the Joint FAO/WHO Expert Committee on Food Additives and the Joint FAO/WHO Meeting on Pesticide Residues to provide risk assessments to the Codex Alimentarius Commission (4). The Committee wished to emphasize the essential role of the expert scientific judgements provided by scientific committees as the basis for risk assessment. Such expertise will be of increasing importance for future developments in understanding the scientific basis of risk assessment, such as mechanisms of toxicity, differences between test species and humans, and human diversity and genetic variability. The Committee will continue to welcome developments in methods of risk assessment which will provide a more sound scientific basis to the advice that it provides to the Codex Alimentarius Commission.

2.3 Principles governing the establishment and revision of specifications

2.3.1 *Significance of identity and purity requirements*

The Committee noted that the specifications monographs contain requirements under two subheadings, “identity tests” and “purity tests”, and it emphasized that substances should meet all require-

ments listed under these headings. The meanings of “identification” and “purity” are both clearly defined in FAO Food and Nutrition Paper No. 5, Rev. 2 (Annex 1, reference 100).

2.3.2 **Limits for arsenic, lead and other heavy metals**

In keeping with its previously stated intentions (Annex 1, references 116 and 122) regarding limits for arsenic, lead and other heavy metals, the Committee considered four issues:

- the lack of specificity in the current limit test for heavy metals (expressed as lead) and the potential loss of metals during the dry ashing procedure, both of which compromise the validity of the test;
- the need to replace the general test for heavy metals with tests for specific metals, particularly for lead, cadmium, mercury and arsenic;
- the need for more specific and sensitive analytical methods, such as atomic absorption spectroscopy (including the graphite furnace technique) and for improved methods of sample preparation; and
- the need to consider the amount of a food additive consumed and its potential for contamination by specific heavy metals.

In order to address these issues in greater depth the Committee will seek information on the specific content of heavy metals in food additives as well as on methods of analysis. At the present meeting, the Committee decided to delete specifications for limits for heavy metals (expressed as lead) from specifications monographs where a specification for lead was available.

2.3.3 **Analytical methods**

Alternative methods

The Committee’s policy has been to describe only one analytical method for an analyte with a limit in the specifications. However, the Committee has now concluded that in some instances the inclusion of alternative methods may be desirable for reasons of economy or simplicity. For example, the use of nuclear magnetic resonance spectroscopy has been presented as an alternative to gas chromatography for the method of assay in the specifications monograph on salatrim, because of the comparative simplicity of the sample preparation and instrumental analysis.

Methods of determining residual solvents and other volatile substances

The Committee observed that a number of specifications require analysis for volatile substances such as residual solvents and reaction

by-products. However, many of the analytical methods are out of date. The Committee wishes to encourage the use of improved techniques such as headspace gas chromatography, and in the future will expect descriptions of such methods to be supplied as part of information for revised or new specifications.

References to standard methods

During the revision of existing specifications the Committee noted that several references have been made to published standard analytical procedures (e.g. American Society for Testing and Materials (ASTM) methods) instead of providing full descriptions of the methods. One such reference was also included in a new monograph prepared at this meeting. The Committee concluded that in future such references should be replaced by a complete description of the methods.

2.3.4 *Enzymes derived from genetically modified organisms*

The Committee designated as “tentative” new specifications for two enzyme preparations derived from genetically modified organisms. This decision was made because Appendix B (General considerations and specifications for enzymes from genetically manipulated microorganisms) to Annex 1 (General specifications for enzyme preparations used in food processing) of the *Compendium of food additive specifications* (Annex 1, reference 96, section 2.3.4), referred to in the specifications, is itself tentative. The Committee decided to review Appendix B at its next meeting in 1998 and subsequently to re-evaluate the specifications for enzyme preparations which refer to Appendix B.

The Committee requested comments on Appendix B, to be reviewed in 1998.

2.3.5 *Flavouring agents*

The Committee was asked to consider the specifications for 224 flavouring agents at the present meeting, of which 60 were transferred to the agenda for a future meeting. It decided to modify the tabular format for the specifications for flavouring agents adopted at the forty-sixth meeting (Annex 1, reference 124). Special methods of analysis and spectra will continue to be included as appendices to the table of flavouring agents. Where a substance has a function in addition to that of a flavouring agent, a standard specification format will be included.

The common names, chemical names and synonyms will be used to index the substances. A new identification number was allocated to

each substance for the convenience of the Committee and an identification number will also be allocated to each substance evaluated in the future. The Committee proposed to develop a classification by chemical group, for ease of future safety evaluations.

2.4 Principles governing intake assessments of food additives and contaminants

The Joint FAO/WHO Expert Consultation on the Application of Risk Analysis to Food Standards Issues (4) recognized that assessments of the intake of food additives, contaminants and residues of pesticides and veterinary drugs should be considered an integral part of the risk assessment process for these substances. At its present meeting, the Committee also recognized the importance of assessments of dietary intake in characterizing any potential risks posed by food additives and contaminants.

2.4.1 *Methods for assessing dietary intake*

The Committee agreed with the conclusion of the FAO/WHO Consultation on Food Consumption and Exposure Assessment to Chemicals (5) that, in principle, the estimation of potential dietary intakes is the same for all food chemicals. However, because of differences in their occurrence in the food supply, assessments of intake of food additives and contaminants may be based on different types of data on consumption of food and on occurrence of chemicals in food. The procedures developed for pesticide residues are applicable to assessments of the dietary intake of contaminants which also occur in raw agricultural commodities (6). These procedures were employed in the assessment of the intake of aflatoxins (section 5).

In most cases, assessments of the intake of food additives are conducted using data on consumption of processed foods. For certain food additives, "poundage" data may be used to estimate per capita intake. Five main approaches for assessing dietary intake of food additives have been used by countries at the national level (7, 8). These approaches usually overestimate chronic (long-term) daily intake, and this could compensate for potential differences in intake between population subgroups and for day-to-day fluctuations in individuals. The five approaches are summarized below.

The budget method

This method takes into account the physiological requirements for energy and fluid in estimating consumption of foods in solid and liquid form. The Committee emphasized that the budget method is

not a procedure for estimating food additive intake *per se*. However, because of its simplicity it is generally accepted as an appropriate screening tool at the international or national level for the identification of food additives that require further assessment.

The "poundage" approach

This approach uses statistics on usage of food additives, adjusted for imports, exports and non-food uses.

The food balance sheet/household survey approach

This method is based on food available for consumption either at a national or household level. Food balance sheets are adjusted for the proportion of each raw commodity that is processed and likely to contain the food additive being studied.

The model diet approach

This method is used to construct a model diet from information on food consumption for a selected population subgroup.

Individual dietary records

These methods use data from representative national surveys of individual food consumption.

These approaches are listed in the order of their increasing ability to accurately predict dietary intake. However, increased accuracy requires more comprehensive data on food consumption and use of food additives as well as greater resources for the assessment of dietary intake. Other approaches for assessing intake such as duplicate diet studies and total diet studies may also be used.

2.4.2 Assessment of dietary intake of specific additives

The Committee was requested at the Twenty-ninth Session of the Codex Committee on Food Additives and Contaminants (2) to perform assessments of the intake of five food additives: benzoic acid and its salts, butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), *tert*-butylhydroquinone (TBHQ) and sulfites. These food additives have been identified for priority assessment by the Codex Committee because initial assessments indicate that intakes of these food additives may approach or exceed the ADIs established by the Expert Committee.

Information on national assessments of the intake of these five food additives will be requested from countries based on procedures developed by the Committee. The Committee recommended that an evaluation of intake assessments from various countries should be

undertaken at the next meeting of the Committee at which food additives and contaminants are considered. The likely intakes of these substances on a global basis will be assessed to respond to the request of the Codex Committee to provide guidance on the potential for the intakes of these food additives to exceed their ADIs.

3. **Specific food additives and food ingredients**

The Committee evaluated three food additives and one food ingredient for the first time and re-evaluated several food additives and aflatoxins considered at previous meetings. In addition, the Committee evaluated a large number of flavouring agents using the Procedure for the Safety Evaluation of Flavouring Agents (section 2.2.1). Information on the evaluations and on specifications is summarized in Annex 2.

3.1 **Antioxidant: *tert*-butylhydroquinone (TBHQ)**

tert-Butylhydroquinone (TBHQ) was previously evaluated by the Committee at its nineteenth, twenty-first, thirtieth, thirty-seventh and forty-fourth meetings (Annex 1, references 38, 44, 73, 94 and 116). At the forty-fourth meeting, the previously established temporary ADI of 0–0.2 mg/kg of body weight was extended, pending results from long-term toxicity studies in rodents. This ADI was derived from a no-observed-effect level (NOEL) of 1500 mg/kg in the diet (equivalent to 37.5 mg/kg of body weight per day) in a 117-week feeding study in dogs on the basis of haematological changes observed at the next highest dose level of 5000 mg/kg in the diet. At its present meeting, the Committee reviewed the results of the long-term toxicity studies in mice and rats. In addition, new information relating to the metabolism of TBHQ, its effects on the induction of enzymes, and its short-term and reproductive toxicity in rodents was available for review. The results from the long-term study in dogs and the genotoxicity studies relating to the clastogenic potential of TBHQ were also re-evaluated.

In studies reviewed at earlier meetings of the Committee (Annex 1, references 39 and 117), TBHQ was shown to be extensively absorbed and rapidly excreted following ingestion by rats, dogs and humans. The major urinary metabolites in all three species were the *O*-sulfate and *O*-glucuronide conjugates, with the former predominating. In numerous *in vitro* studies, TBHQ was shown to induce the activity of phase II enzymes, including glucuronosyl transferase and glutathione transferase, by a mechanism independent of the *Ah* receptor.

Induction of hepatic glutathione transferase activity was also demonstrated following short-term administration of TBHQ in the diet of female mice.

TBHQ also undergoes redox cycling with the corresponding quinone, accompanied by the production of reactive oxygen species. In a study reviewed at the present meeting, three glutathione conjugates of TBHQ were identified in the bile of male rats and sulfur-containing metabolites of TBHQ were detected in the urine. In other studies, glutathione conjugates of TBHQ demonstrated higher redox cycling activity than unconjugated TBHQ, and were toxic to the kidney and bladder when administered intravenously to male rats.

In a new 13-week feeding study conducted in mice, significant treatment-related effects were noted in both sexes. These effects were decreased body-weight gain and hyperplasia of the mucosal epithelium of the forestomach. The latter effect was noted only at very high doses of TBHQ; 20 g/kg in the diet (equal to 4000 mg/kg of body weight per day) and above. The NOEL was 870 mg/kg of body weight per day. In a 13-week feeding study conducted in rats continuously exposed to TBHQ, starting *in utero*, treatment-related haemosiderin pigmentation of the spleen was noted in both sexes. In addition, there was a treatment-related increase in atrophy of the red pulp of the spleen in female rats receiving 2.5 and 5 g/kg in the diet. Bone marrow and haematological parameters were not altered at these doses. Hyperplasia of the forestomach was not observed in this study, even at the highest dose tested; 10 g/kg in the diet (equal to 800 mg/kg of body weight per day), although it has been noted in another study in adult rats following short-term administration of TBHQ at 20 g/kg in the diet. Treatment with TBHQ had no effect on the estrous cycle or on the histological appearance of the reproductive organs. Because pigmentation of the spleen was noted in female rats at the lowest dose tested, a NOEL could not be established, but the lowest-observed-effect level (LOEL) was 190 mg/kg of body weight per day. Irritation and hyperplasia observed in the nasal epithelium of both rats and mice and on the skin of mice were considered to be the consequence of direct contact with TBHQ from the diet.

The results of two recently conducted carcinogenicity studies were reviewed. In female mice, TBHQ induced an increase in the incidence of hyperplasia of the thyroid follicular cells at all dose levels. A non-significant increase in follicular cell adenomas was reported at the highest dose of 5 g/kg in the diet (equal to 600 mg/kg of body weight per day) but the incidence was within the range of historical controls. No follicular cell carcinomas were observed. Decreased body-weight

gains were also observed at the highest dose in both sexes. Since the Committee was aware that hydroquinone (the unsubstituted parent compound) induces thyrotoxicity in mice, but not rats (9), it considered that the hyperplasia of the follicular cells observed with TBHQ in this study might be a toxicologically significant effect. Consequently, it concluded that a NOEL could not be identified in this study and that the lowest dose of 1.25 g/kg in the diet, equal to 130 mg/kg of body weight per day, represented the LOEL. In the study in rats, toxicologically significant effects were noted only at the highest dose tested, 5 g/kg in the diet (equal to 220 mg/kg of body weight per day); these effects were an increase in the incidence of hyperplasia of transitional cells and suppurative inflammation of the kidneys of male rats and haemosiderin pigmentation of the spleen of the females. The Committee considered that 2500 mg/kg in the diet, equal to 110 mg/kg of body weight per day, represented the NOEL and that TBHQ was not carcinogenic in mice or rats.

The 117-week study on dogs in which the temporary ADI had been based was re-evaluated in the light of supplementary information requested from its authors. On the basis of actual intake data, nominal levels of 500, 1580 and 5000 mg/kg in the diet were equal to doses of 21, 72 and 260 mg/kg of body weight per day. In dogs of both sexes given the highest dose, statistically significant reductions in haemoglobin concentrations and erythrocyte volume fractions were observed at several sampling intervals throughout the study, although the values were within the ranges in historical controls. Red blood cell counts were also significantly decreased in male and female dogs in the highest-dose group at week 112, the only time at which measurement of this parameter was reported. Increases in the reticulocyte count (as a percentage of red blood cells) and the presence of immature red blood cell forms in the peripheral blood of animals from all treated groups, reported to occur late in the study, were not dose-related nor were they accompanied by changes in red blood cell parameters at 500 and 1580 mg/kg in the diet. On the basis of this re-evaluation, the Committee confirmed that the NOEL for long-term toxicity in dogs was 1580 mg/kg in the diet, equal to 72 mg/kg of body weight per day.

In view of the conflicting results of the genotoxicity assays reviewed at previous meetings of the Committee, many of the studies of TBHQ were re-evaluated at the present meeting with respect to the validity of the protocol and interpretation of data. The conclusions of a number of the studies could no longer be supported. The results of the well conducted studies indicated that TBHQ was clastogenic *in vitro* in the absence or presence of metabolic activation, but did not induce

the formation of micronuclei *in vivo*. In sister chromatid exchange assays, TBHQ was positive in mice *in vivo* and in an *in vitro* system. The results from several studies suggested that damage to DNA resulting from exposure to TBHQ, including chromosome loss and breakage, was secondary to the production of reactive oxygen species. In the light of this information, and the fact that TBHQ was not carcinogenic in rats or mice, the Committee concluded that TBHQ was unlikely to be genotoxic *in vivo* under conditions of use as an antioxidant, and that further genotoxicity studies were unnecessary.

The results of four reproductive toxicity studies in rats were evaluated. Taken together, the results of these studies indicated an adverse effect of TBHQ on the survival and/or body weight of pups at levels of 5 g/kg in the diet or higher. The effect on pup body weight occurred late in the lactation period. The NOEL was 2.5 g/kg in the diet, equivalent to 125 mg/kg of body weight per day.

On the basis of the data reviewed at the present meeting, the Committee concluded that TBHQ was not carcinogenic in rats or mice. After reviewing the long-term toxicity studies in mice, rats and dogs and the reproductive toxicity studies in rats, the Committee concluded that the most sensitive species was the dog. The Committee allocated an ADI of 0–0.7 mg/kg of body weight for TBHQ, based on the NOEL of 72 mg/kg of body weight per day and a safety factor of 100. The NOEL was rounded to one significant figure, as is the usual practice.

A toxicological monograph incorporating new information and relevant information from the earlier toxicological monographs and monograph addenda was prepared. The existing specifications were revised, with minor changes.

3.2 Emulsifiers

3.2.1 Microcrystalline cellulose

Microcrystalline cellulose was evaluated at the fifteenth, seventeenth and nineteenth meetings of the Committee (Annex 1, references 26, 32 and 38). At the nineteenth meeting, an ADI “not specified” was allocated. In the light of concern about possible persorption and consequential adverse effects of fine particles, the substance was re-evaluated at the present meeting.

In early studies persorption of microcrystalline cellulose was reported in various species including rats. A recent study in which a special

preparation of fine particle size of microcrystalline cellulose (median diameter 6µm) was administered orally to rats (5g/kg of body weight per day) for 90 days has failed to confirm the earlier observations. In this study precautions were taken to ensure that there was no cross-contamination of the tissues with fine particulate matter at autopsy.

In various acute toxicity studies in animals given microcrystalline cellulose parenterally there have been signs consistent with a tissue response to foreign particles. Similarly microcrystalline cellulose has been associated with the formation of granulomas in human lung when it has been injected intravenously by drug abusers. No such lesions have been described as a consequence of oral ingestion of microcrystalline cellulose by rats or humans.

In 90-day toxicity tests during which microcrystalline cellulose was administered to rats at concentrations of 25g/kg to 500g/kg in the diet, increased consumption of food to compensate for the low energy content of this material was observed. Although this may have some adverse effects on mineral absorption there was, in general, no compound-related systemic toxicity. The NOEL was 50g/kg in the diet, equal to 3.8g/kg of body weight per day.

A 2-year study in rats, which were fed microcrystalline cellulose in the diet, was brought to the attention of the Committee. Despite a lack of evidence of toxic effects, the Committee considered that the execution and reporting of the study were not adequate to identify a NOEL. *In vitro* and *in vivo* genotoxicity studies were negative.

In a 3-generation reproductive toxicity study in rats that had been reviewed by the Committee at its fifteenth meeting (Annex 1, reference 27), there were some effects in animals given microcrystalline cellulose at 300g/kg in the diet; these were considered to be a consequence of the quantity of material reducing the energy density of the diet. In recent embryotoxicity and teratogenicity studies in rats, there was no evidence of treatment-related effects at levels of up to 50g/kg in the diet (equal to 4.6g/kg of body weight per day), given on days 6 to 15 of pregnancy.

In some studies in humans there have been reports of alterations in gastrointestinal function following ingestion of microcrystalline cellulose. The changes do not appear to be related to systemic toxicity. The Committee concluded that the toxicological data from humans and animals provided no evidence that the ingestion of microcrystalline cellulose can cause toxic effects in humans when used in foods according to good manufacturing practice.

It is recognized that small particles of other materials may be persorbed and that the extent of persorption is greater with very small particles (<1µm in diameter). Despite the absence of any demonstrated persorption of microcrystalline cellulose in the recent study in rats, the Committee, as a precautionary measure, revised the specifications for microcrystalline cellulose at the present meeting to limit the content of particles less than 5µm in diameter. The Committee retained the ADI “not specified” for microcrystalline cellulose conforming to these specifications.

A toxicological monograph that incorporated the updated earlier monograph and summaries of studies reviewed for the first time at the present meeting was prepared. The existing specifications were revised and the requirement for particle size was changed from “greater than 5µm” to “not more than 10% of the material has a particle size of less than 5µm”.

3.2.2 *Sucrose esters of fatty acids and sucroglycerides*

Sucrose esters of fatty acids and sucroglycerides were previously reviewed by the Committee at its thirteenth, seventeenth, twentieth, twenty-fourth, thirty-fifth, thirty-ninth and forty-fourth meetings (Annex 1, references 19, 32, 41, 53, 88, 101 and 116). At the forty-fourth meeting, the NOEL from a new long-term toxicity/carcinogenicity study in rats was used as the basis for the ADI. The sucrose ester formulations used in this study contained no monoglycerides or diglycerides and the highest dose tested was 50g/kg in the diet, equal to 1970mg/kg of body weight per day. Because the results from a tolerance study in humans raised some concerns about potential laxative effects and related abdominal symptoms, a temporary group ADI of 0–20mg/kg of body weight was established for the sucrose ester content of sucrose esters of fatty acids and sucroglycerides, based on the long-term toxicity study in rats and a safety factor of 100. The results of a well designed and conducted tolerance study in humans were requested for review in 1997.

In the previous study in humans, single doses of 1.5–3.0g, or divided doses of 3.0–4.5g per day for 5–7 days, induced laxation and related abdominal symptoms. The results from a new study in humans indicated an absence of effects of sucrose esters of fatty acids on the frequency and appearance of faeces and related abdominal symptoms in men and women ingesting a divided daily dose of 1.5g of sucrose esters of fatty acids (equal to 27 and 29mg/kg of body weight per day, respectively) for 5 days. Even though the deficiencies in design noted in the earlier study, i.e. the small number of subjects and the lack of

proper controls, were corrected in the new study only a single dose level was used, which was below that previously associated with gastrointestinal disturbances. Consequently, it was not possible to confirm that the effects observed in the previous study were the result of treatment with sucrose esters of fatty acids.

The Committee noted that no systemic effects were observed in a well conducted long-term toxicity study in rats up to the highest dose tested, 1970 mg/kg of body weight per day. Consequently, a group ADI of 0–30 mg/kg of body weight for sucrose esters of fatty acids and sucroglycerides was allocated on the basis of the new study in humans without the application of a safety factor.

An addendum to the toxicological monograph was prepared. The existing specifications for sucrose esters of fatty acids and sucroglycerides were revised, with minor changes.

3.3 Enzyme preparations

3.3.1 α -Acetolactate decarboxylase

α -Acetolactate decarboxylase is an enzyme produced by submerged fermentation of *Bacillus subtilis* carrying the gene coding for α -acetolactate decarboxylase from *B. brevis*. It is used as a processing aid in the brewing and alcohol industry to avoid formation of the unpleasant tasting α -diacetyl from α -acetolactate during fermentation.

α -Acetolactate decarboxylase expressed in *B. subtilis* has not been previously evaluated by the Committee.

Data reviewed by the Committee included information on the pathogenicity of the source and donor organisms as well as short-term toxicity and genotoxicity studies on the enzyme preparation.

Two forms of α -acetolactate decarboxylase have been used in the toxicity studies, namely, an unstabilized form and a glutaraldehyde-stabilized form, which is the form used in the final commercial product.

The available data indicate that both the source organism, *B. subtilis*, and the donor organism, *B. brevis*, are considered to be non-pathogenic species. *B. subtilis* was grown under properly controlled conditions in media containing ingredients commonly used in the production of food-grade substances by fermentation. The vector, pUB110, is a plasmid commonly used in the construction of recombinant microorganisms in the production of enzymes and was not considered to be of toxicological concern.

The pathogenicity of four strains of *B. subtilis* involved either in the construction of the recombinant strain or in the production of α -acetolactate decarboxylase was tested in a study in mice given a single dose by the intraperitoneal route. There were no clinical symptoms related to treatment, and no pathological changes were noted at the end of the study that could be associated with treatment.

The Committee considered the recombinant DNA procedures used, and concluded that the recombinant strain of *B. subtilis* should be regarded as a safe source of α -acetolactate decarboxylase.

Administration of α -acetolactate decarboxylase in the diet to rats in a 14-day and a 13-week study was not associated with any signs of toxicity at dietary levels equivalent to 2500mg/kg in the feed (14-day study) or 500mg/kg in the feed (13-week study) for either the unstabilized or stabilized enzyme. No long-term toxicity studies were available. In genotoxicity studies, negative results were obtained with both unstabilized and stabilized α -acetolactate decarboxylase in *in vitro* gene mutation assays in bacteria and mammalian cells and in a chromosomal aberration assay in human lymphocytes.

On the basis of the toxicological data, the Committee concluded that α -acetolactate decarboxylase is an enzyme of low toxicity and that no further studies are required to assess its safety.

The Committee established a temporary ADI “not specified” for α -acetolactate decarboxylase from this recombinant strain of *B. subtilis* when the preparation is used in accordance with good manufacturing practice. A temporary ADI was allocated, pending consideration of the “tentative” qualification of the specifications.

A toxicological monograph was prepared. New specifications were prepared and designated as “tentative” because of the tentative qualification of Appendix B (General considerations and specifications for enzymes from genetically manipulated microorganisms) to Annex 1 (General specifications for enzyme preparations used in food processing) of the *Compendium of food additive specifications* (Annex 1, reference 96, section 2.3.4).

3.3.2 **Maltogenic amylase**

The enzyme under evaluation is a maltogenic amylase produced by submerged fermentation of a non-pathogenic and non-toxicogenic strain of *Bacillus subtilis* which contains the *amyM* gene from *B. stearothermophilus* coding for maltogenic amylase.

Maltogenic amylase expressed in *B. subtilis* has not been previously evaluated by the Committee.

Formulations of maltogenic amylase are used in the baking and starch industry. It is an exo-acting maltogenic amylase enzyme (EC 3.2.1.133, glucan 1,4- α -maltohydrolase), which catalyses the hydrolysis of 1,4- α -glucosidic linkages in amylose, amylopectin and related glucose polymers. Maltose units are successively removed from the non-reducing end of the polymer chain until the molecule is degraded or, in the case of amylopectin, until a branch point is reached. The Committee noted that the human intake of this recombinant maltogenic amylase resulting from its intended use in the baking and starch industry would be low and that the material consumed would not be the active maltogenic amylase but a heated, denatured material.

The data reviewed included the genetic modification procedures employed, characterization of the producing organisms, the fermentation process, acute and short-term toxicity studies in animals, and genotoxicity studies.

The Committee noted that well documented non-pathogenic and non-toxicogenic strains of microorganisms (*Bacillus subtilis*, *Escherichia coli* K12 and *B. stearothermophilus*) had been used in the genetic modification procedures. The final vector used (pUB110) is well characterized and has been used for several years as a cloning vehicle for *B. subtilis*. The plasmid construct pDN1413, containing the *amyM* gene, was introduced into *B. subtilis* (a derivative of strain 168) using standard transformation procedures. Although the plasmid pDN1413 carries the gene for kanamycin resistance, it is unlikely that this gene can be transferred, since it is well integrated into the host genome and no plasmid DNA could be detected in the end-product. The entire DNA sequence of pDN1413 was determined, which confirmed that genes coding for shiga-like toxins are not present.

B. subtilis was grown under properly controlled conditions in media containing ingredients commonly used in the production of food-grade substances by fermentation.

From the evaluation of the recombinant DNA procedures being employed, the Committee concluded that the final construct should be regarded as a safe source of maltogenic amylase.

The product tested in the toxicological studies was a concentrated material with an enzyme activity of 35900 units/g. It was produced according to the standard production process except that the formulation/standardization step was omitted and the product was lyophilized.

In a 90-day study in which the lyophilized test compound was administered in the diet of rats, the highest dose, 50 g/kg in the diet, caused a significant reduction in body-weight gain accompanied by a slight decrease in food consumption in both males and females. A significant decrease in thyroid weights was also seen in both males and females. At the next dose, 15 mg/kg in the diet, no statistically significant treatment-related findings were observed. The NOEL in this study was 15 g/kg in the diet, equal to 1200 mg/kg of body weight per day.

The test compound had no effects in *in vitro* gene mutation studies in bacteria or mammalian cells, and the results of chromosomal aberration tests *in vivo* and *in vitro* were consistently negative.

The test compound did not cause skin or eye irritation in rabbits and did not produce skin sensitization in a delayed-contact hypersensitivity assay in guinea-pigs.

The Committee allocated a temporary ADI “not specified” to maltogenic amylase derived from this recombinant strain, pending deletion of the “tentative” qualification of the specifications.

A toxicological monograph was prepared. New specifications were prepared and designated as “tentative” because of the tentative qualification of Appendix B (General considerations and specifications for enzymes from genetically manipulated microorganisms) to Annex 1 (General specifications for enzyme preparations used in food processing) of the *Compendium of food additive specifications* (Annex 1, reference 96, section 2.3.4).

3.4 Flavouring agent: *trans*-anethole

trans-Anethole was previously reviewed by the Committee at its eleventh, twenty-third, twenty-seventh, twenty-eighth, thirty-first, thirty-third, thirty-seventh and thirty-ninth meetings (Annex 1, references 14, 50, 62, 66, 77, 83, 94 and 101). At the thirty-seventh meeting, a temporary ADI of 0–0.6 mg/kg of body weight was allocated on the basis of the results of a long-term toxicity/carcinogenicity study in Sprague–Dawley rats. In this study, a dose-related increase in the incidence of non-neoplastic proliferative lesions in the liver was observed in both males and females at all doses. In addition, a clear increase in the incidence of hepatocellular adenomas and carcinomas was observed in female rats receiving *trans*-anethole at the highest level, 10 g/kg in the diet (equal to 550 mg/kg of body weight per day). In male animals a slight increase in the incidence of hepatocellular adenomas but not carcinomas was observed at 10 g/kg in the diet (equal to 400 mg/kg of body weight per day).

At the thirty-ninth meeting, the Committee was informed that comparative metabolic studies in mice and rats, studies on the effects of long-term dietary administration of *trans*-anethole on hepatic enzyme induction and cell proliferation in these species and on enzyme induction in humans, and *in vitro* cytotoxicity and genotoxicity studies were in progress. The temporary ADI was extended to 1997, pending the completion of these studies and the results of a long-term study in mice at appropriate levels to establish a no-effect level.

Not all of the requested studies were available for review at the present meeting. The Committee was informed that further studies would be available by 1998.

The Committee extended the previously allocated temporary ADI of 0–0.6 mg/kg of body weight until 1998, pending the submission of the results of the remaining studies.

No toxicological monograph was prepared. The specifications were revised and, as *trans*-anethole is used only as a flavouring agent, they were transferred to the list of flavouring agents in the *Compendium of food additive specifications, Addendum 5* (FAO Food and Nutrition Paper, No. 52, Add. 5, 1997).

3.5 **Glazing agent: hydrogenated poly-1-decene**

Hydrogenated poly-1-decene has not been previously evaluated by the Committee. It is used as a glazing and releasing agent.

The Committee considered that the data available from a 28-day range-finding study and a 90-day study in which hydrogenated poly-1-decene was administered in the feed of rats were inadequate to support the use of this product as a food additive. Considering the potentially high intake from its use, the Committee concluded that adequate data are required to establish that oily coats observed in rats fed hydrogenated poly-1-decene are not the result of systemic absorption. In addition, data in humans that clearly demonstrate the lack of absorption of this substance should be provided. In the absence of these data, long-term toxicity and reproductive toxicity studies and information on the metabolism, distribution and excretion of hydrogenated poly-1-decene would be required.

A toxicological monograph was not prepared. New specifications were prepared.

3.6 **Sweetening agent: maltitol syrup**

At the present meeting, the Committee reviewed a request for the amendment of the specifications for maltitol syrup in the context of its

toxicological implications. The current specifications (Annex 1, reference 124) to which the ADI “not specified” applies (Annex 1, references 83 and 107) require that maltitol syrup has a maltitol content of no less than 50%, a sorbitol content of no more than 8%, a maltotriitol content of no more than 25% and a content of hydrogenated polysaccharides containing more than three glucose or glucitol units of no more than 30%. An ADI “not specified” was allocated to maltitol syrup produced from glucose syrups that meet these specifications at the thirty-third meeting of the Committee (Annex 1, reference 83) and confirmed at the forty-first meeting (Annex 1, reference 107).

The proposed amendment would support the use of a broader range of starch hydrogenation products than are currently permitted. By deletion of the specification tests for hydrogenated saccharides other than maltitol, while still requiring a maltitol content of no less than 50.0% and a total polyol content of no less than 99.0%, the content of any of these components in maltitol syrup (sorbitol, maltotriitol and higher-order polyols) could theoretically be as high as 49%. Since an ADI “not specified” has been established for both sorbitol and maltitol, the toxicological review concentrated on the consequences of high concentrations of the higher-order hydrogenated saccharides.

The results of metabolic studies in rats and humans indicated that the higher-order polyol components in hydrogenated starch hydrolysates of differing composition were efficiently hydrolysed in the gastrointestinal tract to glucose and a small amount of maltitol. Maltitol was hydrolysed less readily by endogenous enzymes and a considerable portion undergoes fermentation in the lower gastrointestinal tract. The small amount that is absorbed is rapidly excreted unchanged in the urine.

Studies in animals treated with maltitol syrup composed of up to 41% higher-order polyols were reviewed at the twenty-ninth meeting of the Committee (Annex 1, reference 70). At its present meeting, the Committee reviewed the toxic potential of two materials that contain more than 49% of the hydrogenated polysaccharides, the first containing 10% sorbitol, 8% maltitol and 82% higher-order polyols and the second containing 100% hydrogenated dextrin, were evaluated in studies in which they were fed to animals, and the mutagenic potential of hydrogenated dextrin was also examined in bacterial assays. A study in rats showed that ingestion of up to 5.2 g/kg of body weight per day of hydrogenated dextrin for 13 weeks did not result in any treatment-related effects. No treatment-related toxicity was seen in

rats or dogs when the material containing 10% sorbitol, 8% maltitol and 82% higher-order polyols was administered in the diet at dosages of up to 18 and 43 g/kg of body weight per day, respectively, for 90 days. Hydrogenated dextrin was not mutagenic in either *Salmonella typhimurium* or *Escherichia coli* strains in the absence or presence of rat S9 microsomal fraction.

On the basis of the above considerations, the Committee confirmed the previous ADI “not specified” and concluded that it could be applied to maltitol syrup meeting the revised specifications.

An addendum to the toxicological monograph was prepared. In reviewing the specifications for maltitol syrup, the Committee considered the specifications for “hydrogenated saccharides other than maltitol” to be unnecessary and deleted the reference and respective purity test.

3.7 **Miscellaneous substance: salatrim (short- and long-chain acyltriglyceride molecules)**

Salatrim has not been previously reviewed by the Committee. Salatrim is a family of structured triglycerides containing, on average, one or two long-chain fatty acid moieties (usually stearic acid), the remainder being short-chain fatty acids. It is intended for use as a reduced-calorie replacement for conventional fats and oils.

The Committee evaluated studies on the caloric value of salatrim, being aware that short-chain fatty acids supply fewer kilocalories per gram than long-chain fatty acids. However, the claim of poor absorption of stearic acid from salatrim has not been proven for humans. Because there is no specific formulation for salatrim, it is not possible to assign a single caloric value to this product. The Committee noted that the specifications for salatrim that were elaborated at the present meeting permit formulations that include up to 0.87 g of stearate per g of fat. The biological data available do not provide information on materials with such compositions. If future studies determine that stearic acid is poorly absorbed from such formulations, the Committee considered that the consequences of this will need to be determined.

In evaluating the safety of salatrim, the Committee considered various studies. An *in vitro* study with porcine pancreatic lipase demonstrated that a wide range of the salatrim triacylglycerides are hydrolysed rapidly. In rats, the *in vivo* metabolism of a specific salatrim formulation indicated that it was metabolized in an analogous manner to triolein.

Salatrim products do not contain any structural features suggestive of potential mutagenicity, and no evidence of genotoxicity was observed in an adequate range of *in vitro* or *in vivo* studies.

Five 90-day studies in rats, each using a different salatrim formulation administered at concentrations of up to 100 g/kg in the diet, showed no toxicologically significant effects. A 28-day study in minipigs of a specific salatrim formulation was carried out using dose levels of 30, 60 and 100 g/kg in the diet, and also showed no toxicologically significant effects. These studies were not designed to detect potential nutritional effects, and the study in minipigs was of insufficient duration. The Committee concluded that these limitations meant that the studies did not provide an adequate basis for a nutritional or toxicological evaluation.

Because of the high projected intake of salatrim products (90th percentile levels for “all ages” and for 3–5-year-olds are 37 and 26 g per day, respectively) and given that no systemic effects were seen in animal studies, the Committee paid particular attention to the results of the five studies in humans. Of these, one was a free-living trial, the other four were clinic-based with different experimental designs.

In the four clinic-based studies the experimental protocols provided intakes of up to 60 g of salatrim per person per day for periods of 1, 4 or 7 days. Although these studies provided some indication that the consumption of salatrim in the diet was associated with an increased incidence of mild gastrointestinal symptoms and significantly elevated serum enzymes, the treatment periods were short and the numbers of study participants were few.

The free-living study was a randomized, double-blind, multiple-dose, parallel comparison between diets in which the fat was replaced by salatrim oil (23SO, 4SO or 43SO) and control diets in which the fat was soy oil. At least 12 women and 12 men were recruited for each of the two control groups and each of the five treatment groups which received 30, 45 or 60 g per day of 23SO, 60 g per day of 4SO or 60 g per day of 43SO. The total duration of the study was 6 weeks. Subjects in the treatment groups received soy oil during weeks 1 and 6 and salatrim during weeks 2–5, while those in the control groups received soy oil throughout the study.

A total of 183 subjects started the study; 34 dropped out, four of whom were controls. Of those who dropped out, 20 had received salatrim and recorded adverse effects as the reason for leaving the study. The Committee noted inconsistencies between the published

and unpublished reports of the study in that there were differences in the recorded numbers of subjects dropping out.

The consumption of 60 g of salatrim per day was associated with more reports (compared to controls) of stomach cramps and nausea in a substantial number of subjects. Transient elevations of the levels of alanine aminotransferase and aspartate aminotransferase were recorded. Due to the short duration of the study, the high drop-out rate and the modest number of participants, the Committee concluded that it was not possible to determine whether these observations were clinically significant.

The Committee concluded that the available studies did not provide an adequate basis for evaluating the safety and nutritional effects of salatrim. The Committee recommended that additional appropriately designed studies be performed to assess fully both the safety and nutritional consequences of ingestion of salatrim.

A monograph addressing the safety and nutritional effects of salatrim, which included an analysis of the caloric content of the salatrim family, was prepared.

The Committee considered salatrim to be a replacement for conventional fats and oils and therefore regarded it as a food ingredient and not as a food additive. At the request of the Codex Committee on Food Additives and Contaminants the Committee nevertheless prepared new specifications to describe this food ingredient.

4. **Substances evaluated using the Procedure for the Safety Evaluation of Flavouring Agents**

Six groups of flavouring agents were evaluated using the Procedure for the Safety Evaluation of Flavouring Agents as modified at the present meeting (section 2.2.1 and Fig. 1).

The Committee noted that in applying the Procedure, the substance is first assigned to a structural class as identified at the forty-sixth meeting of the Committee (Annex 1, reference 122). The structural classes are as follows:

- Class I. Substances that have simple chemical structures and efficient modes of metabolism which would suggest a low order of oral toxicity.
- Class II. Substances that have structural features that are less innocuous than those of substances in class I, but are not suggestive

of toxicity. Substances in this class may contain reactive functional groups.

- Class III. Substances that have structural features that permit no strong initial presumption of safety, or may even suggest significant toxicity.

A key element of the Procedure involves determining whether a flavouring agent and the product(s) of its metabolism are innocuous and/or endogenous substances. For the purpose of the evaluations, the Committee used the following definitions adapted from the report of its forty-sixth meeting.

Innocuous metabolic products are defined as products that are known or readily predicted to be harmless to humans at the estimated intake of the flavouring agent.

Endogenous substances are intermediary metabolites normally present in human tissues and fluids, whether free or conjugated; hormones and other substances with biochemical or physiological regulatory functions are not included. The estimated intake of a flavouring agent that is, or is metabolized to, an endogenous substance should be judged not to give rise to perturbations outside the physiological range.

The Committee first considered the metabolic pathways common to the groups of flavouring agents evaluated at the present meeting.

Hydrolysis of esters

Linear alkyl esters are hydrolysed rapidly to their component alcohols and carboxylic acids in the intestinal tract, blood and liver, and most tissues throughout the body. Hydrolysis is catalysed by classes of enzymes recognized as carboxylesterases or esterases. For simple linear esters, as considered at this meeting, the rate of hydrolysis increases with increased chain length of either the acid or alcohol component. The rate of hydrolysis of straight-chain esters is approximately 100 times that of branched-chain esters. The rates of hydrolysis of the alkenyl esters citronellyl acetate (3,7-dimethyl-6-octen-1-yl acetate) and citronellyl phenylacetate, by artificial pancreatic juice, were similar to the rates for simple branched-chain esters.

Oxidation of alkyl primary alcohols and aldehydes

Most linear and branched-chain, saturated and unsaturated primary alcohols are oxidized rapidly to their corresponding aldehydes by alcohol dehydrogenase. The rate of oxidation increases with increased chain length, and the presence of a double bond.

The subsequent oxidation of the aldehydes to their corresponding acids is catalysed by dehydrogenase and oxidase enzymes. The most active is a NAD^+/NADH -dependent aldehyde dehydrogenase present in the cytosol, the activity of which increases with increasing relative molecular mass of the aldehyde substrate. Aldehydes may also be reduced to alcohols or conjugated with sulfhydryl-containing substances, such as glutathione. Aldehyde dehydrogenase-catalysed oxidation of aldehydes of low relative molecular mass requires glutathione, which suggests that the free aldehyde may be conjugated rapidly with glutathione *in vivo* to form a thiohemiacetal that is subsequently oxidized to the corresponding acid. Branched-chain aldehydes are rapidly oxidized by aldehyde dehydrogenase, and the rate of oxidation of 2-methylpropanal is similar to that of acetaldehyde.

Oxidation of linear saturated carboxylic acids

Aliphatic linear saturated carboxylic acids are metabolized in the fatty acid β -oxidation pathway, the tricarboxylic acid cycle, or the C_1 -tetrahydrofolate pathway. Oxidation of formic acid to carbon dioxide and water occurs primarily in the liver and is catalysed by tetrahydrofolate in humans and other primates.

Other carboxylic acids are condensed with coenzyme A (CoA) to yield thioesters that undergo β -cleavage to acetyl CoA. Carboxylic acids containing an even number of carbon atoms give acetyl CoA, whereas those containing an odd number yield acetyl CoA and propionyl CoA. Acetyl CoA enters the citric acid cycle directly, whereas propionyl CoA is first converted to succinyl CoA.

Oxidation of branched-chain saturated carboxylic acids

Short-chain (containing six or fewer carbon atoms) branched-chain saturated aliphatic acids undergo β -oxidation preferentially in the longer chain, followed by cleavage to yield linear acid fragments that are metabolized via the fatty acid pathway or the tricarboxylic acid cycle. Isobutyric acid (2-methylpropanoic acid), isovaleric acid (3-methylbutanoic acid) and 2-methylbutyric acid (2-methylbutanoic acid) are formed during the oxidative deamination of endogenous branched-chain amino acids and are metabolized by normal pathways of intermediary metabolism. At high dose levels, longer branched-chain acids may undergo ω -oxidation to yield diacids that undergo further oxidation and cleavage.

Acids with a methyl substituent are extensively metabolized to carbon dioxide via β -oxidation, unless the methyl group is located at the β -position (e.g. 3-methylpentanoic acid), in which case α -oxidation

occurs, yielding short-chain acid fragments capable of being completely metabolized.

The presence of a 2-ethyl substituent prevents the β -oxidation of aliphatic carboxylic acids, and these compounds undergo ω -oxidation and ω -1 oxidation to yield polar metabolites that are excreted primarily in the urine. Saturation of this ω -oxidation pathway may lead to formation of the 2-substituted carboxylic acid that may be excreted as the glucuronic acid conjugate.

4.1 **Allyl 2-furoate**

Twenty-one allyl esters used as flavouring agents in food were evaluated by the Committee at its forty-sixth meeting using the Procedure for the Safety Evaluation of Flavouring Agents modified at that meeting (Annex 1, reference 122). The Committee concluded that the use of 20 of the 21 allyl esters that were evaluated posed no safety concerns at their estimated levels of intake. The evaluation of one of the flavouring agents in the group, allyl 2-furoate (2-propenyl furan-2-carboxylate), was postponed pending consideration of the last step on the right-hand side of the Procedure in which a decision criterion of 1.5 μ g per person per day is applied to a substance for which adequate data on metabolism and toxicity are lacking. At the present meeting, allyl 2-furoate was evaluated in accordance with the Procedure inclusive of this step (see Fig. 1).

Intake data

On the basis of a reported annual volume of production of 1 kg in Europe (International Organization of the Flavor Industry, personal communication, 1995) and <0.01 kg in the USA (10), the estimated daily per capita intake of allyl 2-furoate is 0.14 μ g in Europe and <0.01 μ g in the USA. These estimates were calculated assuming under-reporting of the poundage data and consumption by 10% of the population as described in Annex 5 of WHO Food Additives Series, No. 35 (Annex 1, reference 117).

Information on absorption, metabolism and elimination

No data on the metabolism of allyl 2-furoate, an ester of allyl alcohol and 2-furoic acid, were available. The Committee recognized that allyl esters are generally hydrolysed to allyl alcohol and their corresponding carboxylic acids. At its forty-sixth meeting, however, the Committee determined that there was insufficient evidence to conclude that allyl 2-furoate would be rapidly and completely hydrolysed in humans.

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (see Fig. 1) to allyl 2-furoate, the Committee assigned the compound to structural class III (11).

Step 2. No data on the metabolism of allyl 2-furoate were available and the substance could not be predicted to be metabolized to innocuous products. Accordingly, the right-hand side of the decision tree was further considered.

Step B3. The intake estimates for allyl 2-furoate were below the threshold for class III (90 µg per day).

Step B4. There were no toxicity data on allyl 2-furoate or on a structurally related substance to provide a NOEL to indicate whether an adequate margin of safety exists under conditions of intended use.

Step B5. The conditions of use of allyl 2-furoate do not result in an intake greater than 1.5 µg per day. The estimated intake is approximately one-tenth of this value.

Conclusion

No multiple-dose toxicity studies on allyl 2-furoate were available. At its forty-sixth meeting, the Committee considered the available toxicity data on the other allyl esters as inapplicable to the evaluation of allyl 2-furoate, because they were all expected to be rapidly and completely hydrolysed in humans.

If hydrolysis of allyl 2-furoate were assumed, the ADI for allyl alcohol and knowledge of the metabolism of 2-furoic acid would support a conclusion of no safety concern for this substance. In accordance with the Procedure, the Committee concluded that allyl 2-furoate would not be expected to present a safety concern at the estimated level of current intake.

A toxicological monograph was not prepared. The tentative specifications prepared at the forty-sixth meeting of the Committee were maintained.

4.2 **Saturated aliphatic acyclic linear primary alcohols, aldehydes and acids**

The Committee evaluated a group of 38 flavouring agents that included selected saturated aliphatic acyclic linear primary alcohols, aldehydes and acids of chain length C_{1-18} (Table 1) using the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1).

Table 1
Summary of the results of safety evaluations of 38 saturated aliphatic acyclic linear primary alcohols, aldehydes and acids^a

Substance	No.	Step A3 ^b Does intake exceed the threshold for human intake?	Step A4 Endogenous or metabolized to endogenous substances?	Comments	Conclusion based on levels of current intake
Formic acid ^c	0079	No Europe: 800 USA: 160	NR	Formic acid is produced endogenously in humans and is a normal component of intermediate metabolism	No safety concern
Acetaldehyde	0080	Yes Europe: 11 000 USA: 9700	Yes	Acetaldehyde is oxidized to acetic acid which is metabolized via the citric acid cycle; acetaldehyde can also be reduced to ethanol	
Acetic acid ^c	0081	Yes Europe: ND USA: 360 000	Yes	Acetic acid is metabolized to carbon dioxide; it acetylates amines and can be incorporated into proteins	
Propyl alcohol	0082	Yes Europe: 420 USA: 2700	Yes	Propyl alcohol is oxidized to propionaldehyde which is oxidized to propionic acid; propionic acid is metabolized via the citric acid cycle	
Propionaldehyde	0083	No Europe: 33 USA: 140	NR	Propionaldehyde is oxidized to propionic acid which is metabolized via the citric acid cycle	

Propionic acid ^c	0084	Yes Europe: 1100 USA: 5200	Yes	Propionic acid is metabolized via the citric acid cycle
Butyl alcohol	0085	Yes Europe: 1900 USA: 8100	Yes	Butyl alcohol is oxidized to butyraldehyde which is oxidized to butyric acid; butyric acid is metabolized via the fatty acid and tricarboxylic acid pathways
Butyraldehyde	0086	No Europe: 26 USA: 17	NR	Butyraldehyde is oxidized to butyric acid which is metabolized via the fatty acid and tricarboxylic acid pathways
Butyric acid	0087	Yes Europe: 10000 USA: 5900	Yes	Butyric acid is metabolized via the fatty acid and tricarboxylic acid pathways
Amyl alcohol	0088	No Europe: 97 USA: 44	NR	Amyl alcohol is oxidized to valeraldehyde which is rapidly oxidized to valeric acid; valeric acid is metabolized via the fatty acid and tricarboxylic acid pathways
Valeraldehyde	0089	Yes Europe: 3000 USA: 8.8	Yes	Valeraldehyde is rapidly oxidized to valeric acid which is metabolized via the fatty acid and tricarboxylic acid pathways
Valeric acid	0090	No Europe: 140 USA: 850	NR	Valeric acid is metabolized via the fatty acid and tricarboxylic acid pathways
Hexyl alcohol	0091	Yes Europe: 1900 USA: 800	Yes	Hexyl alcohol is oxidized to hexanal which is rapidly oxidized to hexanoic acid; hexanoic acid is metabolized via the fatty acid and tricarboxylic acid pathways
Hexanal	0092	No Europe: 780 USA: 260	NR	Hexanal is rapidly oxidized to hexanoic acid which is metabolized via the fatty acid and tricarboxylic acid pathways
Hexanoic acid	0093	Yes Europe: 3500 USA: 1300	Yes	Hexanoic acid is metabolized via the fatty acid and tricarboxylic acid pathways

No safety concern

Table 1 (continued)

Substance	No.	Step A3 ^b Does intake exceed the threshold for human intake?	Step A4 Endogenous or metabolized to endogenous substances?	Comments	Conclusion based on current levels of intake
Heptyl alcohol	0094	No Europe: 12 USA: 7	NR	Heptyl alcohol is oxidized to heptanal which is rapidly oxidized to heptanoic acid; heptanoic acid is metabolized via the fatty acid and tricarboxylic acid pathways	No safety concern
Heptanal	0095	No Europe: 200 USA: 3.2	NR	Heptanal is rapidly oxidized to heptanoic acid which is metabolized via the fatty acid and tricarboxylic acid pathways	
Heptanoic acid	0096	No Europe: 170 USA: 5.3	NR	Heptanoic acid is metabolized via the fatty acid and tricarboxylic acid pathways	
1-Octanol	0097	No Europe: 230 USA: 32	NR	1-Octanol is oxidized to octanal which is rapidly oxidized to octanoic acid; octanoic acid is metabolized via the fatty acid and tricarboxylic acid pathways

NR: Not required for evaluation because consumption of the substance was determined to be of no safety concern at step A3 of the procedure. ND: no intake data reported

^a Step 1: All of the substances in this group are in structural class 1, the human intake threshold of which is 1800 µg per day.

^b All intake values are expressed in µg per day.

^c The ADI for this substance was maintained.

Several substances in the group have been evaluated previously by the Committee. At the seventeenth meeting, group ADIs “not limited” were allocated to acetic acid and its potassium and sodium salts and to propionic acid (propanoic acid) and its calcium, potassium and sodium salts, and an ADI of 0–3 mg/kg of body weight was allocated to formic acid (Annex 1, reference 32), which was made a group ADI with ethyl formate at the twenty-third meeting (Annex 1, reference 50). A group ADI of 0–0.1 mg/kg of body weight was established for octanal and nonanal, singly or in combination, at the twenty-eighth meeting (Annex 1, reference 66). An ADI “not limited” was allocated to the aluminium, ammonium, calcium, magnesium, potassium and sodium salts of myristic (tetradecanoic), palmitic (hexadecanoic) and stearic (octadecanoic) acids at the seventeenth meeting (Annex 1, reference 32). At the twenty-ninth meeting, the Committee did not establish ADIs for these acids due to lack of information on the manufacture and use of the food-grade material, but noted that they are normal constituents of coconut oil, butter and other edible oils. ADIs have not been allocated to butyl alcohol (1-butanol), decanal or propyl alcohol (1-propanol) because the data were considered to be inadequate (Annex 1, references 38, 14 and 56 respectively).

The intake of one substance, ethyl alcohol (ethanol), which is structurally related to the group was considered at the forty-sixth meeting (Annex 1, reference 122), when the Committee evaluated ethyl esters used as flavouring agents. At that time, the Committee concluded that ethyl alcohol posed no safety concern at its current level of intake when ethyl esters are used as flavouring agents.

Intake data

The total annual volume of production of the 38 substances from their use as flavouring agents is approximately 2100 tonnes in the USA. Approximately 90% of the total volume is accounted for by acetic acid, which includes the amount produced for uses (acidulant or solvent) in food other than as a flavouring agent. No specific data were available on the use of acetic acid as a flavouring agent in Europe. Disregarding acetic acid, the total reported annual volume of production of the remaining 37 aliphatic substances used as flavouring agents is approximately 300 tonnes in Europe and 200 tonnes in the USA.

According to production statistics and derived estimated intakes of flavouring agents in Europe and the USA, acetaldehyde (ethanal), butyl alcohol and butyric acid (butanoic acid) are the most important substances in this group. Acetaldehyde and butyric acid account for

about 50% of the daily per capita intake in Europe, and acetaldehyde and butyl alcohol account for about 46% of the daily per capita intake in the USA. Other flavouring agents in this group with high intake levels (i.e. >1800 µg per person per day) include octanoic acid, hexanoic acid, valeraldehyde (pentanal), butyl alcohol and hexyl alcohol (1-hexanol) in Europe and butyric acid, propionic acid, propyl alcohol and stearic acid in the USA (Table 1).

Saturated linear aliphatic alcohols, aldehydes and acids are ubiquitous in nature. Alcohols and acids of low relative molecular mass have been detected in almost every known fruit and vegetable. There are a limited number of reports of the natural occurrence of the corresponding aldehydes. In the USA, the available quantitative data indicate that the dietary consumption of saturated linear aliphatic alcohols, aldehydes and acids from naturally occurring sources exceeds their consumption from use as flavouring substances.

Information on absorption, metabolism and elimination

Linear aliphatic acyclic alcohols, aldehydes and carboxylic acids are absorbed through the gastrointestinal tract. Their half-lives in plasma are difficult to measure since many alcohols of low relative molecular mass (e.g. ethyl alcohol), aldehydes and carboxylic acids (e.g. acetic acid and propionic acid) are endogenous in humans. Acetaldehyde has been detected in whole blood (<0.2 mg/l) and acetate is a blood buffer.

The flavouring agents in this group of selected saturated aliphatic linear alcohols, aldehydes and acids are all metabolized via the fatty acid and tricarboxylic acid pathways (see pages 26–27).

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1) to the above-mentioned saturated aliphatic linear alcohols, aldehydes and acids, the Committee assigned all 38 substances to structural class I.

Step 2. All of the flavouring agents in this group are known to be, or can be readily predicted to be, efficiently metabolized to innocuous substances. Accordingly, the left-hand side of the decision tree was further considered.

Step A3. The intake estimates for 27 substances in this group fall below the threshold for human intake for class I (1800 µg per day); therefore, these substances were considered to be of no safety concern.

Step A4. The intake estimates for 11 substances in this group exceeded the threshold for human intake for class I. In all cases, the substances could be predicted to undergo complete metabolism to endogenous products via the fatty acid and tricarboxylic acid pathways. In the opinion of the Committee, the endogenous levels of metabolites from these substances would not give rise to perturbations outside the physiological range. Therefore, these 11 substances were also considered to be of no safety concern.

Table 1 summarizes the evaluation of the 38 saturated aliphatic acyclic linear primary alcohols, aldehydes and acids using the Procedure.

Consideration of combined intakes

In the unlikely event that all foods containing all of the 38 substances in this group were consumed simultaneously on a daily basis, the estimated daily per capita intake in Europe and the USA (excluding intakes of acetic acid and propionic acid which have ADIs “not limited”) would be approximately 40mg and 30mg respectively, i.e. above the threshold for human intake for substances in class I.

All of the substances in this group and their metabolites are innocuous and endogenous and their combined intake was judged by the Committee not to give rise to perturbations outside the physiological range.

Conclusion

The Committee concluded that the substances in this group would not present safety concerns at the estimated current levels of intake.

No toxicity data were required for the application of the Procedure. However, the Committee noted that the toxicity data that were available were consistent with the results of using the Procedure. In cases where ADIs had been established previously, they were maintained at the present meeting.

A monograph summarizing the safety data on this group of flavouring agents was prepared.

4.3 Saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids

The Committee evaluated a group of 25 flavouring agents that included selected saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids (see Table 2) using the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1).

Table 2

2-Methylundecanal	0275	No Europe: 0.61 USA: 0.10	
Structural class II: ethyl-substituted saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids			
2-Ethylbutyraldehyde ^c	0256	No Europe: 0.57 USA: 0.17	No safety concern
2-Ethylbutyric acid ^c	0257	No Europe: 60 USA: 31	
2-Ethyl-1-hexanol ^{c, d}	0267	No Europe: 86 USA: 40	

^a Step 2: All of the substances in this group are metabolized to innocuous products.

^b The thresholds for human intake for classes I and II are 1800 µg per day and 540 µg per day, respectively. All intake values are expressed in µg per day.

^c The 2-ethyl substituent inhibits the β-oxidation of aliphatic alcohols, aldehydes and carboxylic acids. These compounds undergo ω- and ω-1-oxidation to yield polar metabolites which are primarily excreted in urine.

^d The ADI for this substance was maintained.

Twenty-two of these substances contain one or more methyl substituents and the remaining three have ethyl substituents in the α-position.

Two of the substances have been evaluated previously by the Committee. Isobutyl alcohol (2-methyl-1-propanol) was considered at the twenty-third meeting, when an ADI was not allocated because of a

lack of information (Annex 1, reference 50). An ADI of 0–0.5 mg per kg of body weight was allocated to 2-ethyl-1-hexanol at the forty-first meeting (Annex 1, reference 107).

Intake data

The total annual volume of production of the 22 methyl-substituted saturated aliphatic branched-chain primary alcohols, aldehydes and acids from their use as flavouring substances is approximately 29 tonnes in Europe and 9.8 tonnes in the USA. In Europe, more than 85% of the total annual volume is accounted for by five substances (isobutyl alcohol, isobutyric acid, 2-methylbutyric acid, isovaleric acid and 2-methylvaleric acid (2-methylpentanoic acid)). In the USA more than 80% of the total annual volume is accounted for by seven substances (isobutyl alcohol, isobutyraldehyde (2-methylpropanal), isobutyric acid, 2-methylbutyraldehyde (2-methylbutanal), 2-methylbutyric acid, 3-methylbutyraldehyde (3-methylbutanal) and isovaleric acid).

The total reported annual volume of production of the three 2-ethyl substituted substances for use as flavouring agents is 1000 kg in Europe and 370 kg in the USA.

Saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids have been detected as natural components of a wide variety of foods such as cheese, fruits, vinegar and alcoholic beverages. Quantitative data on the natural occurrence of these flavouring agents has been reported for 11 of the 25 substances in the group and their total annual consumption in food is estimated at 1.5 million kg per year.

Information on absorption, metabolism and elimination

The metabolism of methyl- and ethyl-substituted saturated aliphatic acyclic branched-chain alcohols, aldehydes and carboxylic acids is described on pages 26–27.

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1) to the above-mentioned saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids, the Committee assigned all 22 methyl-substituted substances to structural class I. The three ethyl-substituted substances (2-ethylbutyraldehyde (2-ethylbutanal), 2-ethylbutyric acid (2-ethylbutanoic

acid) and 2-ethyl-1-hexanol) contain sterically hindered functional groups and were therefore assigned to structural class II.

Step 2. At their current levels of intake from use as flavouring agents (see Table 2), the 22 methyl-substituted alcohols, aldehydes and carboxylic acids and the three ethyl-substituted alcohols, aldehydes and carboxylic acids would not be expected to saturate the metabolic pathways and all the compounds were predicted to be metabolized to innocuous products.

Step A3. The intake estimates for all the 22 methyl-substituted substances in this group in both Europe and the USA are below the threshold for human intake for class I (1800µg per day). Therefore, these substances were considered to be of no safety concern when used as flavouring agents at current estimated levels of intake.

The intake estimates for the three ethyl-substituted substances (2-ethylbutyraldehyde, 2-ethylbutyric acid and 2-ethyl-1-hexanol) in this group in both Europe and the USA are below the threshold for human intake for class II (540µg per day). Therefore, these substances were also considered to be of no safety concern when used as flavouring agents at current estimated levels of intake.

Table 2 summarizes the evaluation of the 25 saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and carboxylic acids using the Procedure.

Consideration of combined intake

In the unlikely event that all foods containing all 22 methyl-substituted alcohols, aldehydes and acids as flavouring agents were consumed simultaneously on a daily basis, the estimated total daily per capita intake of these substances would be 410µg in Europe and 1900µg in the USA.

In the unlikely event that all foods containing all three ethyl-substituted alcohols, aldehydes and acids were consumed simultaneously on a daily basis, the estimated total daily per capita intake of these three substances would be less than 145µg in Europe and less than 71µg in the USA.

The Committee judged that the combined intake of substances in this group is of no safety concern, since all the substances are expected to be efficiently metabolized and the combined level of intake is not expected to saturate metabolic pathways.

Conclusion

The Committee concluded that the use of the above-mentioned substances as flavouring agents would not present safety concerns at the estimated current levels of intake.

No toxicity data were required for the application of the Procedure. However, the Committee noted that where toxicity data were available they were consistent with the results of the Procedure. The ADI established previously for 2-ethyl-1-hexanol was maintained.

A monograph summarizing the safety data on this group of flavouring agents was prepared.

4.4 Aliphatic lactones

The Committee evaluated a group of 35 aliphatic lactones used as flavouring agents in food (Table 3) using the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1).

Two substances in the group, γ -nonalactone and γ -undecalactone, were previously evaluated by the Committee at its eleventh meeting, when ADIs of 0–1.25 mg/kg of body weight were established for each substance (Annex 1, reference 14).

Intake data

The total annual volume of production of the 35 substances from their use as flavouring agents is approximately 160 tonnes in Europe and 27 tonnes in the USA. The estimated total daily per capita intakes of all aliphatic lactones resulting from their use as flavouring agents are 30.3 mg in Europe and less than 5.3 mg in the USA. In Europe, γ -decalactone and δ -dodecalactone account for two-thirds of the daily per capita intake of lactones used as flavouring agents. In the USA, four substances (γ -decalactone, δ -decalactone, γ -dodecalactone and δ -dodecalactone) account for most of the daily per capita intake of aliphatic lactones used as flavouring agents.

The four lactones that are α,β -unsaturated (5-hydroxy-2,4-decadienoic acid δ -lactone, 5-hydroxy-2-decenoic acid δ -lactone, 5-hydroxy-2-dodecenoic acid δ -lactone, and a mixture of 5-hydroxy-2-decenoic acid δ -lactone, 5-hydroxy-2-dodecenoic acid δ -lactone and 5-hydroxy-2-tetradecenoic acid δ -lactone) and the two hydroxy-furanones (5-ethyl-3-hydroxy-4-methyl-2(5*H*)-furanone and 4,5-dimethyl-3-hydroxy-2,5-dihydrofuran-2-one) are estimated to have very low total daily per capita intakes. The combined estimated per capita intakes of these six substances from their use in food is 27 μ g in Europe and less than 9 μ g in the USA.

^a The thresholds for human intake for classes I and III are 1800 µg per day and 90 µg per day, respectively. All intake values are expressed in µg per day.

^b The ADI for this substance was maintained.

^c Evaluation deferred, pending consideration of other α,β -unsaturated compounds.

Most of the aliphatic lactones have been reported to occur naturally in traditional foods. The four aliphatic lactones that are used most as flavouring agents (γ -decalactone, δ -decalactone, γ -dodecalactone and δ -dodecalactone) are ubiquitous in food, occurring mainly in fruits, alcoholic beverages, meats and dairy products.

Information on absorption, metabolism and elimination

Lactones are generally formed by acid-catalysed intramolecular cyclization of hydroxycarboxylic acids. In an aqueous environment, a pH-dependent equilibrium is established between the open-chain hydroxycarboxylate anion and the lactone ring. In basic media, such as blood, the open-chain hydroxycarboxylate anion is favoured while in acidic media, such as urine, the lactone ring is favoured. Both the aliphatic lactones and the ring-opened hydroxycarboxylic acids can be absorbed from the gastrointestinal tract.

The aliphatic lactones in this group can be divided into three subgroups on the basis of their predicted metabolism, namely, lactones derived from linear and branched-chain hydroxycarboxylic acids, lactones which are α,β -unsaturated, and the two hydroxyfuranones. The metabolism of the members of each of these subgroups is discussed below.

Lactones derived from linear saturated 5-hydroxycarboxylic acids.

Linear saturated 5-hydroxycarboxylic acids (formed from δ -lactones) are converted, via acetyl CoA, to hydroxythioesters which then undergo β -oxidation and cleavage to yield an acetyl CoA fragment and a new β -hydroxythioester reduced by two carbons. Acids containing even numbers of carbon atoms continue to be oxidized and cleaved to yield acetyl CoA while those containing odd numbers of carbon atoms yield acetyl CoA and propionyl CoA. Acetyl CoA enters the citric acid cycle directly while propionyl CoA is transformed into succinyl CoA which then enters the citric acid cycle.

Lactones derived from linear saturated 4- or 6-hydroxycarboxylic acids.

Linear saturated 4- or 6-hydroxycarboxylic acids (formed from γ - or ϵ -lactones) participate in the same pathway as described above for linear saturated 5-hydroxycarboxylic acids; however, loss of an acetyl CoA fragment produces an α -hydroxythioester which undergoes α -oxidation and α -decarboxylation to yield a linear carboxylic acid and eventually carbon dioxide. γ -Butyrolactone, the only lactone in this group formed from a primary alcohol, may participate in an alternative oxidation pathway, namely, oxidation by alcohol dehydrogenase and succinate-semialdehyde dehydrogenase to succinate which then enters the citric acid cycle.

Lactones derived from linear unsaturated hydroxycarboxylic acids. If the lactone is formed from a linear hydroxycarboxylic acid which is unsaturated, cleavage of acetyl CoA units continues along the carbon chain until the position of unsaturation is reached. If the unsaturation begins at an odd-numbered carbon, acetyl CoA fragmentation will eventually yield a 3-enoyl CoA which is converted to the *trans*- Δ^2 -enoyl CoA before entering the fatty acid pathway. If unsaturation begins at an even-numbered carbon, acetyl CoA fragmentation yields a Δ^2 -enoyl CoA product which is a substrate for further fatty acid oxidation. If the stereochemistry of the double bond is *cis*, hydration yields (*R*)-3-hydroxyacyl CoA which is isomerized to (*S*)-3-hydroxyacyl CoA by 3-hydroxyacyl CoA epimerase prior to entering the fatty acid pathway.

Lactones derived from branched-chain hydroxycarboxylic acids. For branched-chain hydroxycarboxylic acids, the principal metabolic pathways utilized for detoxication are influenced by the chain length and the position and size of the alkyl substituents. Short-chain (< six carbon atoms) branched aliphatic hydroxycarboxylic acids may be excreted unchanged as the glucuronic acid conjugate, or undergo α - or β -oxidation followed by cleavage and complete metabolism to carbon dioxide via the fatty acid pathway and the tricarboxylic acid cycle. Alternatively, as chain length, substitution and lipophilicity increase, the hydroxycarboxylic acid may undergo a combination of ω -, ω -1 and β -oxidation to yield polar hydroxyacid, ketoacid and hydroxydiacid metabolites which are excreted as the glucuronic acid or sulfate conjugates in the urine and, to a lesser extent, in the faeces. These metabolites are considered to be innocuous.

α,β -Unsaturated lactones. For the four substances which are α,β -unsaturated there was no direct evidence of hydrolysis. While hydrolysis to the corresponding ring-opened α,β -unsaturated hydroxycarboxylic acids may occur, no information was available on the four substances considered to enable the Committee to predict that this is the major route of metabolism. If hydrolysis to the corresponding ring-opened form occurs, condensation of the α,β -unsaturated hydroxycarboxylic acid with acetyl CoA would yield a Δ^2 -enoyl CoA product, which is a substrate in the fatty acid pathway. Since the stereochemistry of the double bond in a lactone is *cis*, hydration would yield (*R*)-3-hydroxyacyl CoA, which is then isomerized to (*S*)-3-hydroxyacyl CoA by 3-hydroxyacyl CoA epimerase prior to entering the fatty acid pathway.

Alternatively, the lactones which are α,β -unsaturated may conjugate with glutathione and be excreted as cysteine or mercapturic acid

derivatives. Evidence for this alternative pathway comes from two structurally related lactones which are α,β -unsaturated. The Committee considered that further information was required in order to clarify the metabolic route(s) of these substances.

Hydroxyfuranones. There was no direct evidence available of hydrolysis of the two hydroxyfuranones (nos 0222 and 0243, see Table 3) to the corresponding ring-opened compound. The Committee considered that alternative metabolic pathways are likely and that no prediction of a metabolic route is possible for these substances.

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1) to the aliphatic lactones, the Committee assigned 29 substances to structural class I; the four α,β -unsaturated substances and the two hydroxyfuranones were assigned to structural class III.

Step 2. The available data indicate that for the 29 lactones in class I derived from saturated linear and branched-chain hydroxycarboxylic acids, the corresponding aliphatic hydroxycarboxylic acids are metabolized via the fatty acid pathway. For these substances, the evaluation should proceed via the left-hand side of the decision-tree. For the four lactones in class III which are α,β -unsaturated, metabolism may occur either via hydrolysis followed by β -oxidation or via conjugation with glutathione. There was insufficient information available to predict the route of metabolism of these four substances with confidence. The Committee considered that further information on their metabolism was required and that they should be evaluated together with other α,β -unsaturated substances and that their evaluation should therefore be deferred. No information was available to indicate the route of metabolism for the two lactones in class III which are hydroxyfuranones and therefore the evaluation of these two substances should proceed via the right-hand side of the decision-tree.

Step A3/B3. For the 29 lactones derived from saturated linear and branched-chain hydroxycarboxylic acids in class I, three lactones (γ -decalactone, δ -decalactone and δ -dodecalactone) had intake estimates equal to or greater than the threshold for class I (1800 μg per day). The evaluation of these three substances therefore proceeded to step A4. For the other 26 lactones of similar structure the intake estimates are below the threshold for class I and they would therefore not be expected to be of safety concern. For the two hydroxyfuranones in class III, the intake estimates are well below the

threshold for class III (90µg per day). The evaluation of these substances therefore proceeded to step B4.

Step A4. None of the three lactones derived from saturated linear hydroxycarboxylic acids (γ-decalactone, δ-decalactone and δ-dodecalactone) are known to be endogenous or to be metabolized to endogenous substances. The safety evaluation of these substances therefore proceeded to step A5.

Step A5. Although adequate studies on which to base a NOEL for the three lactones derived from saturated linear hydroxycarboxylic acids were not available, the following NOELs have been reported for structurally related lactones in 2-year studies in rats: 250mg/kg of body weight per day for γ-nonolactone and γ-undecalactone and 110mg/kg of body weight per day for γ-butyrolactone. In a 2-year study in mice with γ-butyrolactone a NOEL of 260mg/kg of body weight per day was found. The studies on γ-nonolactone and γ-undecalactone were considered previously by the Committee and ADIs were established at the eleventh meeting (Annex 1, reference 14). Although these studies were not conducted according to modern standards, the results are considered to be valid. These NOELs provide an adequate margin of safety (>1000) for γ-decalactone, δ-decalactone and δ-dodecalactone and therefore these substances would not be expected to be of safety concern.

Step B4. The Committee considered the results of studies on the two hydroxyfuranones in class III. In a 90-day study in rats administered 5-ethyl-3-hydroxy-4-methyl-2(5H)-furanone in the diet, the NOEL was 1.3mg/kg of body weight per day, and in a 1-year study in rats administered 4,5-dimethyl-3-hydroxy-2,5-dihydrofuran-2-one in the diet, the NOEL was 46mg/kg of body weight per day. These NOELs provide an adequate margin of safety (>1000) for these substances and therefore they would not be expected to be of safety concern.

Table 3 summarizes the evaluation of the 35 aliphatic lactones using the Procedure.

Consideration of combined intakes

From the available data, the 29 lactones derived from linear and branched-chain hydroxycarboxylic acids would be expected to be efficiently metabolized via commonly known biochemical pathways to innocuous substances. In the unlikely event that all foods containing all 29 substances as flavouring agents were consumed simultaneously on a daily basis, the estimated daily per capita consumption in Europe and the USA would exceed the threshold for human intake for substances in class I but, in the opinion of the Committee, this

would not give rise to perturbations outside the physiological range.

For the two hydroxyfuranones whose route of metabolism is unknown, their combined estimated intake was very low (15 µg per day) compared to the known NOELs for each of these substances and was not considered to present a safety concern.

Conclusions

The Committee concluded that the evaluation of the four substances which are α,β -unsaturated should be deferred, pending consideration of other α,β -unsaturated substances. The safety evaluation of the two hydroxyfuranones proceeded because of the existence of supporting data from toxicity studies.

On the basis of the results of the evaluation of the 29 lactones derived from linear and branched-chain hydroxycarboxylic acids and the substances 5-ethyl-3-hydroxy-4-methyl-2(5*H*)-furanone and 4,5-dimethyl-3-hydroxy-2,5-dihydrofuran-2-one, the Committee concluded that the use of these substances as flavouring agents would not present safety concerns at the estimated current levels of intake.

In using the Procedure, the Committee noted that where toxicity data were available, they were consistent with the results of the safety evaluation.

The ADIs for γ -nonalactone and γ -undecalactone were maintained.

A monograph summarizing the safety data available on this group of flavouring agents was prepared.

4.5 Esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids

The Committee evaluated a group of 32 flavouring agents that included selected esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids (Table 4) using the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1).

The Committee had previously evaluated one member of the group, ethyl isovalerate, at its eleventh meeting (Annex 1, reference 14), but because of a lack of data, was unable to allocate an ADI.

Intake data

The total annual volume of production of the 32 esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids from their use as flavouring substances is approximately 32 tonnes in Europe and 16 tonnes in the USA. In Europe, more than 90% of the

NR: not required for evaluation because consumption of the substance was determined to be of no safety concern at step A3 of the procedure.

^a Step 1: All of the esters in this group are in structural class I.

Step 2: All of the esters in this group are metabolized to innocuous products.

^b The threshold for human intake for class I is 1800 µg per day. All intake values are expressed in µg per day.

^c The components ethanol and 2-methylbutyric acid are endogenous. The acid is an intermediate in the metabolism of the amino acid.

total annual volume is accounted for by ethyl isobutyrate (ethyl 2-methylpropanoate), ethyl isovalerate (ethyl 3-methylbutanoate), ethyl 2-methylbutyrate (ethyl 2-methylbutanoate) and methyl 2-methylbutyrate (methyl 2-methylbutanoate). In the USA, approximately 67% of the total annual volume is accounted for by ethyl isobutyrate, ethyl isovalerate, butyl isovalerate (butyl 3-methylbutanoate) and ethyl 2-methylbutyrate.

Esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids have been detected as natural components of a wide variety of foods. The available quantitative data on the natural occurrence of these esters indicate that the total intake from natural food sources is approximately 14 tonnes per year. This estimated intake is approximately equal to the estimated intake from their use as flavouring substances. In the USA, the consumption of isobutyrate esters from natural food sources is equivalent to their consumption from use as flavouring substances. The consumption of isovalerate esters and 2-methylbutyrate esters from natural food sources is several orders of magnitude higher than that from their use as flavouring agents.

Information on absorption, metabolism and elimination

It is expected that the esters in this group will be readily hydrolysed to their component alcohols and carboxylic acids in the intestinal tract, blood and liver. The metabolism of the hydrolysis products is discussed on pages 26–27.

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1) to the above-mentioned esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids, the Committee assigned all 32 substances to structural class I.

Step 2. At the estimated current levels of intake (see Table 4), these esters would not be expected to saturate the metabolic pathways, and they were all predicted to be metabolized to innocuous products. The left-hand side of the decision-tree was therefore considered.

Step A3. The estimated daily per capita intakes of all but one of the 32 esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids in Europe and the USA were below the threshold for class I (1800 µg per day), so that they were considered to be of no safety concern when used at estimated current levels of

intake as flavouring agents. Only ethyl 2-methylbutyrate has an estimated intake greater than the threshold for class I.

Step A4. Ethyl 2-methylbutyrate is expected to be hydrolysed to ethyl alcohol and 2-methylbutyric acid, which are endogenous. Therefore, this substance was determined to be of no safety concern on the basis of its structural class and known metabolism.

Table 4 summarizes the evaluation of the 32 esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids used as flavouring substances.

Consideration of combined intakes

In the unlikely event that all foods containing all of the substances in this group as flavouring agents were consumed simultaneously on a daily basis, the estimated total daily per capita intake would be 4.6 mg in Europe and 3 mg in the USA. The estimated daily per capita intake of the branched-chain acids (i.e. isobutyric acid, isovaleric acid and 2-methylbutyric acid) formed via hydrolysis of these esters is 3.1 mg in Europe and 2 mg in the USA.

These estimated combined intakes would exceed the threshold for class I. Since all the 32 substances in this group are expected to be efficiently metabolized, they would not be expected to saturate the metabolic pathways. On the basis of the evaluation of the collective data, the Committee concluded that combined intake of these substances would not be expected to be of safety concern.

Conclusion

The Committee concluded that the substances in this group would not present safety concerns at the estimated current levels of intake.

No toxicity data were required for application of the Procedure. However, the Committee noted that where toxicity data were available, they were consistent with the results of the Procedure.

A monograph summarizing the safety data on this group of flavouring agents was prepared.

4.6 Esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids

The Committee evaluated a group of 67 esters of aliphatic linear and branched-chain saturated and monounsaturated primary alcohols

with aliphatic linear saturated carboxylic acids (see Table 5) using the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1).

One member of the group, butyl acetate, had been previously evaluated at the eleventh meeting of the Committee, but no ADI was established due to a lack of data (Annex 1, reference 14).

Intake data

The total annual volume of production of the 67 esters in this group for use as flavouring agents is approximately 65 tonnes in Europe and 19 tonnes in the USA. In Europe, more than 75% of the total annual volume of production is accounted for by butyl butyrate (*n*-butyl *n*-butanoate), *n*-amyl butyrate (pentyl butanoate) and the acetate esters of methyl alcohol (methanol), butyl alcohol, hexyl alcohol, *cis*-3-hexenol and isobutyl alcohol. In the USA, more than 70% of the total annual volume of production is accounted for by *n*-amyl butyrate, *cis*-3- and *trans*-2-hexenyl propionate (*cis*-3- and *trans*-2-hexenyl propanoate) and the acetate esters of propyl alcohol, isobutyl alcohol and 2-methylbutyl alcohol (2-methylbutanol). On the basis of the reported annual volume of production in Europe and the USA, the total estimated daily per capita intake of the 67 esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids from their use as flavouring agents is 9.2mg in Europe and 3.8mg in the USA. The use of seven of the esters (heptyl formate, octyl propionate (octyl propanoate), decyl propionate (decyl propanoate), decyl butyrate (decyl butanoate), butyl heptanoate, butyl laurate (butyl dodecanoate), and *cis*-3- and *trans*-2-hexenyl propionate) has been reported in the USA but not in Europe.

Esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids are principal components of alcoholic beverages and of a wide variety of fruits. Quantitative data on the natural occurrence in food for 37 substances in the group have been reported from the USA, which indicate that the intake of these substances from natural sources exceeds the intake from their use as flavouring agents.

Information on absorption, metabolism and elimination

In general, it is expected that esters of aliphatic linear and branched-chain primary alcohols with aliphatic linear saturated carboxylic acids would be hydrolysed to their component alcohols and carboxylic acids. The metabolism of the saturated acids and alcohols is described on pages 26–27.

Esters of the three monounsaturated alcohols in this group are expected to be oxidized via their corresponding aldehydes to carboxylic

^a Step 1: All of the esters in this group are in structural class I except 2-ethylbutyl acetate, which is in structural class II.

Step 2: Evaluation of *cis*-3- and *trans*-2-hexenyl propionate was postponed. All of the other substances in this group are metabolized to innocuous products.

^b The thresholds for human intake for classes I and II are 1800 µg per day and 540 µg per day, respectively. All intake values are expressed in µg per day.

^c Hexanoic acid, the metabolite of the component hexyl alcohol, and acetic acid are endogenous in humans.

^d Evaluation postponed, pending consideration of other α,β -unsaturated carbonyl compounds.

acids, which then undergo β -oxidation in the fatty acid and other well-known metabolic pathways.

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1) to the above-mentioned esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids, the Committee assigned all but one of the 67 esters to structural class I. 2-Ethylbutyl acetate contains a sterically hindered functional group and was therefore assigned to structural class II.

Step 2. At this step the evaluation of *cis*-3- and *trans*-2-hexenyl propionate was postponed, pending consideration of other α,β -unsaturated carbonyl compounds.

The available data indicate that the remaining esters in this group would be hydrolysed in humans to their component alcohols and carboxylic acids. The aliphatic acyclic primary alcohols are oxidized to their corresponding carboxylic acids, which are either conjugated and excreted in the urine, or undergo β -oxidation and cleavage. The aliphatic linear saturated carboxylic acids are endogenous in humans. At the current levels of per capita intake these esters would not be expected to saturate the metabolic pathways. Therefore, the remaining 66 esters of aliphatic acyclic primary alcohols with aliphatic linear

saturated carboxylic acids were predicted to be metabolized to innocuous products. Accordingly, the Committee considered the left-hand side of the decision-tree.

Step A3. The estimated daily per capita intakes of all but one of the remaining 65 class I esters in this group in Europe and the USA were below the threshold for human intake (1800 µg). Only hexyl acetate had an estimated daily per capita intake greater than the threshold for class I. The estimated daily per capita intake of 2-ethylbutyl acetate in Europe and the USA was below the threshold for human intake for class II (540 µg).

Step A4. This step was considered only for hexyl acetate which was the only substance in this group for which the estimated level of intake exceeded the threshold for class I. The component hexyl alcohol is oxidized to hexanoic acid which is endogenous as it is an intermediary metabolite in the fatty acid pathway, and acetate is a component of the tricarboxylic acid cycle. In the opinion of the Committee the endogenous levels of these two metabolites would not give rise to perturbations outside the physiological range. Therefore, hexyl acetate was also determined to be of no safety concern on the basis of its structural class and known metabolism.

Table 5 summarizes the evaluation of the 67 esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids used as flavouring substances.

Consideration of combined intakes

In the unlikely event that all foods containing all of the 66 esters evaluated as flavouring substances were consumed simultaneously on a daily basis, the estimated daily per capita intake in Europe and the USA would exceed the threshold for human intake for substances in class I. All the flavouring agents in this group of esters are expected to be metabolized via well-known biochemical pathways to innocuous metabolites and/or endogenous substances and in the opinion of the Committee the endogenous levels of these metabolites would not give rise to perturbations outside the physiological range. Accordingly, the combined intake of these substances was considered to be of no safety concern.

Conclusions

On the basis of the results of the Procedure, the Committee concluded that the 66 esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids evaluated pose no safety concern when used at the estimated levels of current intake as

flavouring agents. The evaluation of *cis*-3- and *trans*-2-hexenyl propionate was postponed, pending consideration of other α,β -unsaturated carbonyl compounds.

No toxicity data were required for the application of the Procedure for this group of esters. However, the Committee noted that where toxicity data were available, they were consistent with the results of the Procedure.

A monograph summarizing the safety data on this group of flavouring agents was prepared.

4.7 **Esters derived from branched-chain terpenoid alcohols and aliphatic acyclic carboxylic acids**

A safety evaluation of a group of 26 terpenoid esters used as flavouring agents (see Table 6) was conducted using the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1).

One member of the group, geranyl acetate (*trans*-3,7-dimethyl-2,6-octadien-1-yl acetate), was previously evaluated at the twenty-third meeting of the Committee (Annex 1, reference 50). It was evaluated as part of a group of other terpenoid flavouring substances, citral, citronellol and linalool, which have close chemical, biochemical and toxicological relationships. The Committee allocated a group ADI of 0–0.5 mg/kg of body weight, expressed as citral, to these substances on the basis of their clearly defined metabolism and their low toxicity in short-term toxicity studies.

Intake data

The total annual volume of production of the 26 terpenoid esters used as flavouring agents is approximately 13 tonnes in Europe and 2 tonnes in the USA. In both Europe and the USA approximately 60% of the total annual volume is accounted for by the acetate and butyrate esters of citronellol, geraniol and nerol. On the basis of these annual volumes of production, the total estimated daily per capita intake of the 26 terpenoid esters used as flavouring substances is 1800 µg in Europe and 410 µg in the USA. The total estimated daily per capita intake of the terpenoid alcohols (i.e. citronellol, geraniol, nerol and rhodinol) formed via hydrolysis of these esters is 1400 µg in Europe and 320 µg in the USA.

Terpenoid esters are principal flavour components of citrus fruit and citrus peel oils, and have also been detected in a wide variety of other fruits, spices and vegetables. The terpenoid esters are usually found at concentrations of up to 1 mg/kg in citrus fruit juices, 20 g/kg in citrus

^a Step 1: All of the esters in this group are in structural class I.

Step 2: All of the esters in this group are metabolized to innocuous products.

^b The threshold for human intake for class I is 1800 µg per day. All intake values are expressed in µg per day.

^c The ADI for this substance was maintained.

peel oils and 50 g/kg in spices. In the USA terpenoid esters are consumed predominantly as components of traditional foods and the total annual volume of consumption of the most common terpenoid esters as natural components of food is estimated to be approximately 300 tonnes (Stofberg & Grundschober, personal communication, 1987).

Information on absorption, metabolism and elimination

The terpenoid esters are hydrolysed to their corresponding terpenoid alcohols (geraniol, citronellol, nerol and rhodinol) and aliphatic carboxylic acids (formic, acetic, propionic, butyric, valeric, hexanoic,

isobutyric and isovaleric acids). Both the hydrolysis and the metabolism of aliphatic carboxylic acids are discussed on pages 26–27.

Following hydrolysis, the terpenoid alcohols undergo a complex pattern of alcohol oxidation, ω -oxidation, hydration, selective hydrogenation and subsequent conjugation to form oxygenated polar metabolites which are excreted primarily in the urine. Geraniol, related terpenoid alcohols (citronellol and nerol) and the aldehydes (geranial and neral) follow similar metabolic pathways in animals (Fig. 2).

Application of the Procedure

Step 1. In applying the Procedure for the Safety Evaluation of Flavouring Agents (Fig. 1) to the above-mentioned terpenoid esters, the Committee assigned all 26 esters to structural class I.

Step 2. The esters in this group are expected to be readily hydrolysed to their component alcohols and carboxylic acids, which are considered to be innocuous. The terpenoid alcohols are expected to undergo ω -oxidation and functional group oxidation to yield polar metabolites which are excreted as the glucuronic acid conjugate in the urine. Eight of the nine component carboxylic acids are endogenous in humans and are metabolized in the fatty acid β -oxidation pathway, amino acid pathways, the citric acid cycle or the C_1 -tetrahydrofolate pathway to eventually yield carbon dioxide and water. The remaining carboxylic acid, 2-ethylbutyric acid, undergoes oxidation to polar metabolites which are conjugated with glucuronic acid and excreted. At current levels of intake these esters and their component terpenoid alcohols and aliphatic carboxylic acids would not be expected to saturate these metabolic pathways.

Step A3. The daily per capita intakes of each of the 26 terpenoid esters in both Europe and the USA are below the threshold for class I (1800 μ g). Therefore none of the 26 terpenoid esters evaluated were considered to pose a safety concern when used at current levels of intake as flavouring substances.

Table 6 summarizes the evaluation of the 26 terpenoid esters used as flavouring substances.

Consideration of combined intake

In the unlikely event that all foods containing these 26 terpenoid esters used as flavouring agents were consumed simultaneously on a daily basis, the estimated total daily per capita intake would still be below the threshold for human intake for class I (1800 μ g). The

Figure 2
Metabolism of geraniol in rats

Committee noted that the terpene alcohols, geraniol, citronellol and linalool, are used as flavouring agents and that the combined intakes of these alcohols and esters would be less than the group ADI.

Conclusions

The Committee concluded that the esters derived from branched-chain terpenoid alcohols and aliphatic acyclic linear and branched-chain carboxylic acids present no safety concern at the estimated levels of current intake.

No toxicity data were required for the application of the Procedure. However, the Committee noted that where toxicity data were available, they were consistent with the results of the Procedure.

The Committee noted that some of the esters are metabolized to α,β -unsaturated carbonyl compounds, but concluded that these had been adequately evaluated previously (Annex 1, reference 50). The Committee maintained the group ADI of 0–0.5 mg/kg of body weight for geranyl acetate, citral, citronellol and linalool.

A monograph summarizing the safety data on this group of flavouring agents was prepared.

4.8 Specifications for flavouring agents

The specifications for 173 flavouring agents on the modified agenda were reviewed. New specifications were prepared for 153 flavouring agents, 28 of which were designated as "tentative". The existing specifications for 11 flavouring agents reviewed toxicologically and for two flavouring agents reviewed for specifications only (see section 6) were revised. In addition, the existing specifications for the 52 flavouring agents in FAO Food and Nutrition Paper, No. 52, Add. 4 (Annex 1, reference 124) were given identification numbers.

5. Contaminants: aflatoxins

Aflatoxins B₁, B₂, G₁ and G₂ are mycotoxins that may be produced by three species of *Aspergillus*: *A. flavus*, *A. parasiticus* and *A. nomius*, which contaminate plants and plant products. Aflatoxins M₁ and M₂, the hydroxylated metabolites of aflatoxins B₁ and B₂, may be found in milk or milk products obtained from livestock that have ingested contaminated feed. Of these six aflatoxins, aflatoxin B₁ is the most frequently present in contaminated samples and aflatoxins B₂, G₁ and G₂ are generally not reported in the absence of aflatoxin B₁. Most of the toxicological data relate to aflatoxin B₁. Intake of aflatoxins in the diet arises mainly from eating contaminated maize and groundnuts and their products.

The aflatoxins were evaluated at the thirty-first meeting of the Committee (Annex 1, reference 77). At that time, the Committee considered aflatoxins to be potential human carcinogens. Sufficient information was not available to establish a figure for a tolerable level of intake. The Committee urged that the intake of dietary aflatoxins be reduced to the lowest practicable levels so as to reduce the potential risk as far as possible. A working group convened by the International Agency for Research on Cancer also concluded that naturally occurring aflatoxins are carcinogenic to humans (12).

At its forty-sixth meeting (Annex 1, reference 122), the Committee considered estimates of the carcinogenic potency of aflatoxins and the potential risks associated with their intake. In view of the value of such estimates, the Committee recommended that this task be continued at its next meeting and that a monograph be published summarizing the data and analyses.

At its present meeting, the Committee reviewed a wide range of studies in both animals and humans that provided qualitative and quantitative information on the hepatocarcinogenicity of aflatoxins. The Committee evaluated the potency of these contaminants, linked these potencies to intake estimates and discussed the impact of hypothetical standards on sample populations and their overall risks.

Carcinogenicity

The aflatoxins are among the most potent mutagenic and carcinogenic substances known. Extensive experimental evidence from test species shows that aflatoxins are capable of inducing liver cancer in most animal species studied. In addition, most epidemiological studies show a correlation between exposure to aflatoxin B₁ and an increased incidence of liver cancer. Aflatoxins are metabolized in humans and test species to the corresponding epoxide which is usually considered to be the ultimate reactive intermediate. There is some evidence suggesting that humans are at substantially lower risk from exposure to aflatoxins than test species. The Committee was aware of epidemiological studies which suggest that intake of aflatoxins poses no detectable independent risk and of studies which suggest that they pose risks only in the presence of other risk factors such as hepatitis B infection. Several current studies are likely to allow more accurate estimates of the risks to humans from the intake of aflatoxins, most notably cohort studies in China (Qidong and Shanghai) and Thailand and hepatitis B vaccination trials in China (Qidong and Taiwan) and the Gambia. When these studies are complete, the Committee may wish to re-evaluate the risks of aflatoxins in humans.

A number of factors influence the risk of primary liver cancer, most notably carriage of hepatitis B virus as determined by the presence in serum of the hepatitis B surface antigen (presence denoted HBsAg⁺ and absence denoted HBsAg⁻). The potency of aflatoxin B₁ appears to be significantly enhanced in individuals with simultaneous hepatitis B infection. This interaction makes it difficult to interpret the epidemiological studies to determine the extent to which aflatoxins act as independent risk factors. The conclusions of the Committee regarding the carcinogenic potency of aflatoxins are therefore contingent upon the dynamics of hepatitis B infection in a human population.

The identification of hepatitis C virus is an important recent advance in understanding the etiology of liver cancer. Two studies have inves-

tigated interactions between hepatitis C infection, aflatoxins and liver cancer, but the results so far are inconclusive. It is estimated that between 50 and 100% of cases of liver cancer are associated with persistent infection with hepatitis B and/or hepatitis C.

The Committee considered that the weight of scientific evidence, which includes epidemiological data, studies in laboratory animals and *in vivo* and *in vitro* studies of metabolism, supports a conclusion that aflatoxins should be treated as carcinogenic food contaminants, the intake of which should be reduced to levels as low as reasonably achievable.

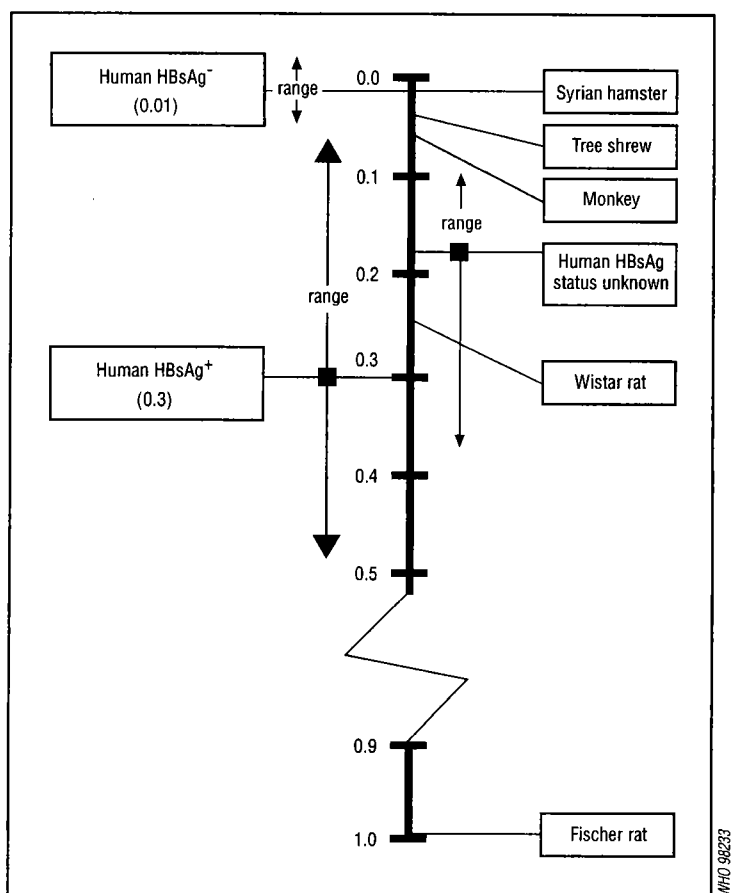

Carcinogenic potency

The Committee reviewed dose–response analyses that have been performed on aflatoxins. All of these analyses have limitations, three of which predominate. First, all of the epidemiological data from which a dose–response relationship can be determined are confounded by concurrent infection with hepatitis B. The epidemiological data are from geographical areas where both the prevalence of HBsAg⁺ individuals and of contamination with aflatoxins are high; the relationship between these risk factors in areas in which aflatoxin contamination and prevalence of hepatitis B are low is unknown. Second, the reliability and precision of the estimates of exposure to aflatoxins in the relevant study populations are unknown. For example, aflatoxin biomarkers in humans do not reflect long-term intake of aflatoxins; analyses of crops for aflatoxins do not reflect the levels of aflatoxins consumed in foods after selection and processing. Finally, the shape of the dose–response curve is unknown and this introduces an additional element of uncertainty when choosing mathematical models for interpolation.

Observations concerning the interaction between hepatitis B infection and aflatoxins suggest two separate aflatoxin potencies; one is apparent in populations in which chronic hepatitis infections are common, the other in populations in which chronic hepatitis infections are rare. In analyses based on toxicological and epidemiological data, potency estimates for aflatoxins were divided into two basic groups, potencies applicable to individuals without hepatitis B infection and those applicable to individuals with chronic hepatitis B infection. The Committee found these estimates useful even though, through the use of differing mathematical models, they covered a broad range of possible values (Fig. 3). Potencies calculated from epidemiological studies in which hepatitis B infection status was unknown were in the range of potencies found in individuals with and without hepatitis B infection. The review also considered the extrapolation of animal data

Figure 3

Potency estimates for human liver cancer resulting from exposure to aflatoxin B₁ (cases per year/100 000 people per ng of aflatoxin B₁/kg of body weight per day), based on epidemiological and toxicological studies

HBsAg⁺: Hepatitis B surface antigen detected in serum; HBsAg⁻: hepatitis B surface antigen not detected in serum.

to estimate potency in humans; these estimates also generally fell within the range of the potency estimates derived from the epidemiological data.

There are several potential biases in the potency estimates depicted in Fig. 3:

- Only studies showing a positive association between aflatoxins and liver cancer were used as opposed to considering all studies (negative as well as positive); this leads to overestimation of the aflatoxin potency.

- When current levels of intake (i.e. using biomarkers or dietary surveys) are related to current levels of liver cancer (which presumably has a long induction period), historical levels of intake are ignored, and since intakes are likely to have been higher in the past, aflatoxin potency will be overestimated.
- The earliest studies systematically underestimated the prevalence of hepatitis B infection in patients with liver cancer by as much as 20–30% due to limitations in the methodology used to detect hepatitis B virus, which also leads to an overestimate of the relative potency of any other factor, including aflatoxins.
- Histological confirmation of the cases of liver cancer is limited in most epidemiological studies, allowing the possibility that cases of non-primary liver cancer have been included, which could lead to an underestimation or overestimation of the aflatoxin potency.

When these biases are taken into account, the values in Fig. 3 should be viewed as overestimates of the potency of the aflatoxins, leading to the hypothesis that it is possible that humans are in fact less sensitive to aflatoxins than the animal species tested in laboratory experiments.

The Committee reviewed the extensive data available on the metabolism of aflatoxins in various species. It was agreed that differences in the carcinogenic potency of aflatoxins between species can be partially attributed to differences in metabolism. However, there was insufficient quantitative information available about competing aspects of metabolic activation and detoxification of aflatoxin B₁ in various species to identify an adequate animal model for humans and to explain the apparent differences in potency between species.

The intake assessments used in many of the epidemiological studies ignored the contributions to total aflatoxin intake made by milk and milk products. Thus, the potencies shown in Fig. 3 do not generally apply to aflatoxin M₁. The results of a comparative toxicity study in rats suggest that aflatoxin M₁ has a potency approximately one order of magnitude less than that of aflatoxin B₁ in this species.

The Committee reviewed the potency estimates from the epidemiological studies which showed a positive association between aflatoxins and liver cancer and chose separate potency estimates and ranges for HBsAg⁺ and HBsAg⁻ individuals. Potency values of 0.3 cancers per year/100 000 population per ng of aflatoxins/kg of body weight per day (range 0.05–0.5) for HBsAg⁺ individuals and of 0.01 cancers per year/100 000 population per ng of aflatoxins/kg of body weight per day (range 0.002–0.03) in HBsAg⁻ individuals were chosen.

Population risks

The fraction of the incidence of liver cancer in a population attributable to intake of aflatoxins was derived by combining estimates of aflatoxin potency (risk per unit dose) and estimates of aflatoxin intake (dose per person). The Committee reviewed the frequency and amount of aflatoxin contamination in a variety of products (e.g. groundnuts, cereals and maize) in numerous countries. Many of the data on levels of aflatoxin contamination were derived from non-random samples which appeared to be biased upwards because monitoring studies focus on products that are thought to be contaminated. Some of the data on levels of contamination are not likely to be based on current Codex Alimentarius Commission sampling recommendations for aflatoxins. Accordingly, data on levels of contamination should be interpreted with caution and used only to infer patterns of importance in setting standards and not to provide exact contamination estimates.

The Committee considered the possible impact of applying hypothetical standards to aflatoxin contamination. It noted that the magnitude of the difference between two hypothetical standards is substantially larger than the magnitude of the difference in the mean contamination levels resulting from application of the separate standards. For example, in the case of maize from the USA, which has a mean level of aflatoxin contamination of 4.7 µg/kg, application of a hypothetical standard of 20 µg/kg would result in rejection of 3.9% of the crop and a mean level of aflatoxin contamination of 0.9 µg/kg. Imposition of a stricter hypothetical standard of 10 µg/kg would result in rejection of 6.2% of the crop and reduce the mean level of aflatoxin contamination by 0.3 µg/kg to 0.6 µg/kg (Table 7). Similar results would be obtained if aflatoxin B₁ levels in maize and total aflatoxins or aflatoxin B levels in groundnuts were examined.

Using the Global Environment Monitoring System–Food Contamination Monitoring and Assessment Programme regional diets combined with data on levels of aflatoxin contamination, the Committee was able to provide relative estimates of the mean dietary intake of aflatoxins for various regions. If these intakes are linked to the potency estimates shown in Fig. 3, it is possible to calculate the overall population risks on the basis of the prevalence of hepatitis B infection in various regions.

From its analysis the Committee noted that the application of a standard would prevent human consumption of the most highly contaminated samples, thus greatly reducing average estimated intakes of aflatoxins. The use of standards by all countries should be encour-

Table 7

Distribution of total aflatoxin contamination in maize from the USA and comparison of the impact of two different hypothetical standards on the percentage of samples rejected and the mean contamination level

Concentration of total aflatoxins in maize (µg/kg)	Percentile	Impact of hypothetical standard on percentage of samples rejected and mean contamination level ^a
0.1	10.0	
0.2	30.0	
0.3	50.0	
0.4	70.0	
0.5	80.0	
1.0	88.0	
5.0	90.6	
10	93.8	6.2% of samples rejected at a standard of 10 µg/kg (mean contamination level = 0.6 µg/kg)
15	95.0	
20	96.1	3.9% of samples rejected at a standard of 20 µg/kg (mean contamination level = 0.9 µg/kg)
30	96.8	
40	97.6	
50	98.0	

^a The mean level of aflatoxin contamination with no standard was 4.7 µg/kg.

aged. The Committee considered the effect of modifying a given standard through the use of several hypothetical calculations. Two illustrations are given below.

The first example pertains to areas in which the level of contamination of food by aflatoxins is low and the proportion of the population who are HBsAg⁺ is small. For this purpose, monitoring data from Europe on aflatoxin B₁ levels in groundnuts, maize¹ and their products were used. In this example, 1% of the population were assumed to be HBsAg⁺. From the potency estimates given earlier (see Fig. 3), this yields an estimated potency for this population of $0.01 \times 99\% + 0.3 \times 1\% = 0.013$ cancers per year/100 000 people per ng of aflatoxins/kg of body weight per day (range 0.002–0.035). If it is assumed that all samples with levels of contamination above 20 µg/kg are removed and that these foods are ingested according to the “European diet”, the mean estimated intake of aflatoxins is 19 ng per person per day. Assuming that an adult human weighs 60 kg, the estimated population

¹ The Committee noted that the aflatoxin data for Europe were for “all cereals”. However, in these calculations, it was assumed that the aflatoxin level for “all cereals” applied to maize only.

risk (potency \times intake) is 0.0041 cancers per year per 100 000 people (range 0.0006–0.01). In contrast, if the same assumptions are used but a hypothetical standard of 10 $\mu\text{g}/\text{kg}$ is applied, the average aflatoxin intake is 18 ng per person per day, resulting in an estimated population risk of 0.0039 cancers per year per 100 000 people (range 0.0006–0.01). Thus, reducing the hypothetical standard from 20 $\mu\text{g}/\text{kg}$ to 10 $\mu\text{g}/\text{kg}$ yields a reduction in the estimated population risk of approximately two cancers per year per 1000 million people.

The second example pertains to areas with higher levels of aflatoxin contamination (for these purposes monitoring data from China on aflatoxin B₁ levels in groundnuts, maize and their products were used) and where a larger percentage of the population are carriers (in this case, 25% were assumed to be HBsAg⁺). The estimated potency for this population is $0.01 \times 75\% + 0.3 \times 25\% = 0.083$ cancers per year per ng of aflatoxins ingested/kg of body weight per day (range 0.014–0.15). If a hypothetical standard of 20 $\mu\text{g}/\text{kg}$ and the “Far Eastern diet” are used, the average estimated intake is 125 ng per person per day, yielding an average population risk of 0.17 cancers per year per 100 000 people (range 0.03–0.3). If a hypothetical standard of 10 $\mu\text{g}/\text{kg}$ is used, the average estimated intake falls to 103 ng per person per day, yielding an estimated population risk of 0.14 cancers per year per 100 000 people (range 0.02–0.3). Thus, reducing the hypothetical standard for this population from 20 $\mu\text{g}/\text{kg}$ to 10 $\mu\text{g}/\text{kg}$ yields a reduction in the estimated population risk of 300 cancers per year per 1000 million people.

Conclusions

1. Aflatoxins are considered to be human liver carcinogens. Aflatoxin B₁ is the most potent carcinogen of the aflatoxins and most of the toxicological data available are related to aflatoxin B₁. Aflatoxin M₁, the hydroxylated metabolite of B₁, has a potency approximately one order of magnitude less than that of B₁.
2. The potency of aflatoxins in HBsAg⁺ individuals is substantially higher than in HBsAg[−] individuals. Thus, reduction of the intake of aflatoxins in populations with a high prevalence of HBsAg⁺ individuals will result in a greater reduction in liver cancer rates than reduction of the intake of aflatoxins in populations with a low prevalence of HBsAg⁺ individuals.
3. Vaccination against hepatitis B will reduce the number of carriers of the virus. The present analysis suggests that reducing the number of carriers would reduce the potency of the aflatoxins in vaccinated populations and consequently reduce the risk of liver cancer.

4. Analyses of the application of hypothetical standards for aflatoxin contamination in food (10 µg/kg or 20 µg/kg) to model populations indicates that:
 - (a) populations in which the prevalence of HBsAg⁺ individuals is low and/or in which the mean intake of aflatoxins is low (less than 1 ng/kg of body weight per day) are unlikely to exhibit detectable¹ differences in population risks;
 - (b) populations in which both the prevalence of HBsAg⁺ and the intake of aflatoxins are high would benefit from reductions in aflatoxin intake.
5. The Committee has previously noted that reductions in the intake of aflatoxins can be achieved through avoidance measures such as improved farming and proper storage practices and/or through enforcing standards for levels of contamination in food or feed within countries and across borders (Annex 1, reference 77).
6. When two alternative standards for aflatoxin contamination in food are being considered, if the fraction of the samples excluded under the two standards is similar, the higher standard will yield essentially the same risk of liver cancer as the lower standard. When a substantial fraction of the current food supply is heavily contaminated with aflatoxins, reducing the levels of contamination may result in a detectable¹ reduction in rates of liver cancer. Conversely, when only a small fraction of the current food supply is heavily contaminated, reducing the standard by an apparently substantial amount may have little appreciable effect on health.

6. Revision of certain specifications

A total of 40 substances were examined for specifications only (see Annex 2), and the specifications for 30 were revised.

The specifications for agar, carthamus yellow, microcrystalline wax, propylene glycol, propylene glycol alginate and gellan gum were revised, with minor changes.

The specifications for alginic acid, ammonium alginate, calcium alginate, potassium alginate and sodium alginate were revised and the requirements for relative molecular mass range were changed in

¹ In the context of this statement "detectable" refers to an aflatoxin-induced change in liver cancer rates which exceeds the year-to-year variability around the current incidence and mortality rates. Hence "detectable" refers to the ability to observe a significant effect on the occurrence of liver cancer following intervention and will depend on the quality of the data available on historical trends in incidence and mortality.

order to reflect more precisely the products on the market. Some minor changes were also made.

The specifications for aluminium powder, mixed carotenoids, ethyl hydroxyethyl cellulose, propylene glycol esters of fatty acids and talc were revised and the "tentative" qualifications were deleted.

The specifications for citric acid, calcium propionate (calcium propanoate), potassium propionate (potassium propanoate) and sodium propionate (sodium propanoate) were revised, with minor changes. Citric acid was also added to the section on flavouring agents in the specifications monograph.

The specifications for propionic acid used as a preservative and an antimould and antirope agent were revised and designated as "tentative". The Committee requested information on the method of analysis and levels of readily oxidizable substances.

The Committee agreed to revise the specifications for modified starches to include enzyme treatment as an alternative method for modifying food starches. In addition, the Committee agreed to delete the minimum and maximum levels of reagents used in the processing of the starches since the end-product specifications were deemed sufficient to assure the quality and safety of the various modified starches. As a result of these recommendations, the existing tentative monograph for enzyme-treated starches was withdrawn.

The specifications for allyl cyclohexane propionate, ethyl octanoate, ethyl nonanoate, isoamyl acetate, isoamyl butyrate, isoamyl isobutyrate and isoamyl isovalerate used as flavouring agents were reviewed and given identification numbers. The specifications for isoamyl acetate used as a carrier solvent were revised in order to reflect that the substance is a mixture.

The existing tentative specifications for carbon dioxide and sulfur dioxide were revised in order to define purer products and the "tentative" designation was deleted.

The specifications for gum arabic obtained from certain species of acacia trees were last revised at the forty-fourth meeting of the Committee (Annex 1, reference 116). In revising the specifications for gum arabic at its present meeting, the Committee considered two new extensive project reports from FAO (13, 14) on the production, marketing and physicochemical characterization of this substance. The reports demonstrated that chemometric analysis of analytical compositional data is a suitable procedure for evaluating the chemical rela-

tionship of gums obtained from various acacia species. In the light of these reports, the Committee reiterated that gum from other acacia species closely related to *Acacia senegal* and meeting the newly revised specifications would adequately reflect the materials that had been toxicologically evaluated. The specifications were revised to make a clear distinction between gum arabic obtained from *A. seyal* and from *A. senegal*.

New specifications for enzyme-hydrolysed sodium carboxymethyl cellulose were prepared and designated as “tentative”. The Committee requested information on the physical state of the substance as manufactured, the nature and proportion of material of low relative molecular mass present in the substance, and tests that distinguish the substance from sodium carboxymethyl cellulose.

The existing tentative specifications for carthamus red were revised and the “tentative” designation was maintained. The Committee requested information on the content of carthamin and method of assay.

The existing tentative specifications for petroleum jelly were revised, with minor corrections, and the “tentative” designation was maintained. The Committee requested information on the method of analysis and levels of viscosity at 100 °C, carbon number at 5% distillation point, average relative molecular mass and oil content. Unless this information was received by 31 March 1998, the specifications would be withdrawn.

The Committee compared the specifications for “diacetyltartaric and fatty acid esters of glycerol” (DATEM) with the existing tentative specifications for “tartaric, acetic and fatty acid esters of glycerol, mixed” and noted that the substances appear very similar. Both substances were toxicologically evaluated at the seventeenth meeting of the Committee in 1973 (Annex 1, reference 32). At that meeting, DATEM was assigned an ADI of 0–50 mg/kg of body weight, whereas the mixed tartaric, acetic and fatty acids of glycerol were assigned an ADI “not limited”. The Committee has not received information which would allow these substances to be distinguished analytically. The Committee decided to maintain the tentative status of the existing specifications for “tartaric, acetic and fatty acid esters of glycerol, mixed” and requested data that would distinguish this substance from DATEM. Unless such data were provided by 31 March 1998, the Committee would consider combining the two specifications. The existing specifications of DATEM were revised.

The Committee withdrew the tentative specifications for anoxomer since none of the information requested at its twenty-sixth meeting (Annex 1, reference 59) has been submitted. The Committee was informed that anoxomer has been neither produced nor used for many years.

The specifications for turmeric as a food colour were on the agenda for revision. However, as the use of this substance was considered to be as a spice and not as a food colour, the Committee decided to withdraw the specifications.

7. Recommendations

1. In view of the large number of food additives, food ingredients and contaminants requiring evaluation or re-evaluation, the important role that the recommendations of the Committee play in the development of international food standards and of regulations in many countries, and the need for maintaining consistency and continuity within the Committee, it is strongly recommended that meetings of the Joint FAO/WHO Expert Committee on Food Additives continue to be held at least once yearly to evaluate these substances.
2. One of the substances referred to the present meeting for evaluation is an example of materials that have been defined as "novel foods" by some countries and organizations. The Committee recommended that FAO and WHO arrange at future meetings of the Committee for the review of procedures outlined in Environmental Health Criteria, No. 70, *Principles for the safety assessment of food additives and contaminants in food* (Annex 1, reference 76) for the safety evaluation of these types of products and for the development of guidelines for assessing their safety and wholesomeness, taking into account guidelines developed by other organizations.

Acknowledgement

The Committee wishes to thank Dr P. Jenkins, International Programme on Chemical Safety, WHO, Geneva, Switzerland, for his assistance in the preparation of the report.

Annex 2

Acceptable Daily Intakes, other toxicological information, and information on specifications

Substance	Specifications ^a	Acceptable Daily Intake (ADI) in mg/kg of body weight and other toxicological recommendations
Antioxidant		
<i>tert</i> -Butylhydroquinone (TBHQ)	R	0–0.7
Emulsifiers		
Microcrystalline cellulose	R	Not specified ^{b, c}
Sucrose esters of fatty acids and sucroglycerides	R	0–30 (group ADI)
Enzyme preparations		
α -Acetolactate decarboxylase	N, T	Not specified (temporary) ^{b, d}
Maltogenic amylase	N, T	Not specified (temporary) ^{b, d}
Flavouring agent		
<i>trans</i> -Anethole	R	0–0.6 (temporary) ^e
Glazing agent		
Hydrogenated poly-1-decene	N	No ADI allocated because insufficient data were available
Sweetening agent		
Maltitol syrup	R	Not specified ^{b, c}
Miscellaneous substance		
Salatrim (short- and long-chain acyltriglyceride molecules)	N	Adequate information was not available to evaluate its safety and nutritional effects

^a N, new specifications prepared; R, existing specifications revised; T, the existing, new or revised specifications are tentative and comments are invited.

^b ADI "not specified" is used to refer to a food substance of very low toxicity which, on the basis of the available data (chemical, biochemical, toxicological and other) and the total dietary intake of the substance arising from its use at the levels necessary to achieve the desired effect and from its acceptable background levels in food does not, in the opinion of the Committee, represent a hazard to health. For that reason, and for reasons stated in individual evaluations, the establishment of an ADI expressed in numerical form is not deemed necessary. An additive meeting this criterion must be used within the bounds of good manufacturing practice, i.e. it should be technologically efficacious and should be used at the lowest level necessary to achieve this effect. It should not conceal food of inferior quality or adulterated food, and it should not create a nutritional imbalance.

^c This ADI applies to the substance conforming to the revised specifications.

^d Temporary ADI, pending consideration of the "tentative" qualification of the specifications. The "tentative" qualification of Appendix B (General considerations and specifications for enzymes from genetically manipulated microorganisms) to Annex 1 (General specifications for enzyme preparations used in food processing) of the *Compendium of food additive specifications* (Rome, Food and Agriculture Organization of the United Nations, 1992) will be reviewed in 1998.

^e Temporary ADI extended to 1998, pending the submission of the results of studies currently underway that were requested at earlier meetings of the Committee.

Flavouring agents

The substances listed here were evaluated using the Procedure for the Evaluation of Flavouring Agents. For further details, see section 2.2.1 of the main report.

Substance ^a	No.	Specifications ^b	Conclusion based on current levels of intake
------------------------	-----	-----------------------------	--

Allyl ester

Allyl 2-furoate (2-propenyl furan-2-carboxylate)	0021	S, T	No safety concern
--	------	------	-------------------

Saturated aliphatic acyclic linear primary alcohols, aldehydes and acids

Formic acid ^c	0079	R	No safety concern
Acetaldehyde (ethanal)	0080	N	
Acetic acid ^c	0081	R	
Propyl alcohol (1-propanol)	0082	R	
Propionaldehyde (propanal)	0083	N	
Propionic acid ^c (propanoic acid)	0084	N	
Butyl alcohol (1-butanol)	0085	R	
Butyraldehyde (butanal)	0086	N	
Butyric acid (butanoic acid)	0087	N	
Amyl alcohol (1-pentanol)	0088	N	
Valeraldehyde (pentanal)	0089	N	
Valeric acid (pentanoic acid)	0090	N	
Hexyl alcohol (1-hexanol)	0091	N	
Hexanal	0092	N	
Hexanoic acid	0093	N	
Heptyl alcohol (1-heptanol)	0094	N	
Heptanal	0095	N	
Heptanoic acid	0096	N	
1-Octanol	0097	N	
Octanal ^c	0098	R	
Octanoic acid	0099	N	
Nonyl alcohol (1-nonanol)	0100	N	
Nonanal ^c	0101	R	
Nonanoic acid	0102	N	
1-Decanol	0103	N	
Decanal	0104	R	
Decanoic acid	0105	N	
Undecyl alcohol (1-undecanol)	0106	N	
Undecanal	0107	N	
Undecanoic acid	0108	N	
Lauryl alcohol (1-dodecanol)	0109	N	
Lauric aldehyde (dodecanal)	0110	N	
Lauric acid (dodecanoic acid)	0111	N	
Myristaldehyde (tetradecanal)	0112	N	
Myristic acid (tetradecanoic acid)	0113	N	
1-Hexadecanol	0114	N	
Palmitic acid (hexadecanoic acid)	0115	N	
Stearic acid (octadecanoic acid)	0116	N	

Saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids

Structural class I: methyl-substituted saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids

Isobutyl alcohol (2-methyl-1-propanol)	0251	NR	No safety concern
Isobutyraldehyde (2-methylpropanal)	0252	NR	
Isobutyric acid (2-methylpropanoic acid)	0253	NR	
2-Methylbutyraldehyde (2-methylbutanal)	0254	NR	

Substance ^a	No.	Specifications ^b	Conclusion based on current levels of intake
2-Methylbutyric acid (2-methylbutanoic acid)	0255	NR	No safety concern
3-Methylbutyraldehyde (3-methylbutanal)	0258	NR	
Isovaleric acid (3-methylbutanoic acid)	0259	NR	
2-Methylpentanal	0260	NR	
2-Methylvaleric acid (2-methylpentanoic acid)	0261	NR	
3-Methylpentanoic acid	0262	NR	
3-Methyl-1-pentanol	0263	NR	
4-Methylpentanoic acid	0264	NR	
2-Methylhexanoic acid	0265	NR	
5-Methylhexanoic acid	0266	NR	
3,5,5-Trimethyl-1-hexanol	0268	NR	
3,5,5-Trimethylhexanal	0269	NR	
2-Methyloctanal	0270	NR	
4-Methyloctanoic acid	0271	NR	
3,7-Dimethyl-1-octanol	0272	NR	
2,6-Dimethyloctanal	0273	NR	
4-Methylnonanoic acid	0274	NR	
2-Methylundecanal	0275	NR	

Structural class II: ethyl-substituted saturated aliphatic acyclic branched-chain primary alcohols, aldehydes and acids

2-Ethylbutyraldehyde (2-ethylbutanal)	0256	NR	No safety concern
2-Ethylbutyric acid (2-ethylbutanoic acid)	0257	NR	
2-Ethyl-1-hexanol ^c	0267	NR	

Aliphatic lactones

Structural class I

4-Hydroxybutyric acid lactone (γ -butyrolactone)	0219	NR	No safety concern
γ -Valerolactone	0220	NR	
γ -Hexalactone	0223	NR	
δ -Hexalactone	0224	NR	
γ -Heptalactone	0225	NR	
γ -Octalactone	0226	NR	
δ -Octalactone	0228	NR	
γ -Nonalactone ^c	0229	NR	
Hydroxynonanoic acid δ -lactone	0230	NR	
γ -Decalactone	0231	NR	
δ -Decalactone	0232	NR	
ϵ -Decalactone	0241	NR	
γ -Undecalactone ^c	0233	NR	
5-Hydroxyundecanoic acid δ -lactone	0234	NR	
γ -Dodecalactone	0235	NR	
δ -Dodecalactone	0236	NR	
ϵ -Dodecalactone	0242	NR	
δ -Tetradecalactone	0238	NR	
ω -Pentadecalactone	0239	NR	
4-Hydroxy-3-pentenoic acid lactone	0221	NR	
5-Hydroxy-7-decenoic acid δ -lactone	0247	NR	
5-Hydroxy-8-undecenoic acid δ -lactone	0248	NR	
1,4-Dodec-6-enolactone	0249	NR	
ω -6-Hexadecenlactone	0240	NR	
4,4-Dibutyl- γ -butyrolactone	0227	NR	

Substance ^a	No.	Specifications ^b	Conclusion based on current levels of intake
3-Heptyldihydro-5-methyl-2(3 <i>H</i>)-furanone	0244	NR	No safety concern
4-Hydroxy-3-methyloctanoic acid γ -lactone	0437	NR	
6-Hydroxy-3,7-dimethyloctanoic acid lactone	0237	NR	
γ -Methyldecalactone	0250	NR	
Structural class III			
5-Hydroxy-2-decenoic acid δ -lactone	0246	NR	Not evaluated ^d
5-Hydroxy-2,4-decadienoic acid δ -lactone	0245	NR	
Mixture of 5-hydroxy-2-decenoic acid δ -lactone, 5-hydroxy-2-dodecenoic acid δ -lactone and 5-hydroxy-2-tetradecenoic acid δ -lactone	0276	NR	
5-Hydroxy-2-dodecenoic acid δ -lactone	0438	NR	
5-Ethyl-3-hydroxy-4-methyl-2(5 <i>H</i>)-furanone	0222	NR	No safety concern
4,5-Dimethyl-3-hydroxy-2,5-dihydrofuran-2-one	0243	NR	

Esters of aliphatic acyclic primary alcohols with branched-chain aliphatic acyclic acids

Methyl isobutyrate (methyl 2-methylpropanoate)	0185	N	No safety concern
Ethyl isobutyrate (ethyl 2-methylpropanoate)	0186	N	
Propyl isobutyrate (<i>n</i> -propyl 2-methylpropanoate)	0187	N	
Butyl isobutyrate (butyl 2-methylpropanoate)	0188	N	
Hexyl isobutyrate (hexyl 2-methylpropanoate)	0189	N	
Heptyl isobutyrate (heptyl 2-methylpropanoate)	0190	N	
<i>trans</i> -3-Heptenyl 2-methylpropanoate	0191	N	
Octyl isobutyrate (octyl 2-methylpropanoate)	0192	N	
Dodecyl isobutyrate (dodecyl 2-methylpropanoate)	0193	N	
Isobutyl isobutyrate (2-methylpropyl 2-methylpropanoate)	0194	N	
Methyl isovalerate (methyl 3-methylbutanoate)	0195	N	
Ethyl isovalerate (ethyl 3-methylbutanoate)	0196	R	
Propyl isovalerate (propyl 3-methylbutanoate)	0197	N	
Butyl isovalerate (butyl 3-methylbutanoate)	0198	N	
Hexyl 3-methylbutanoate	0199	N	
Octyl isovalerate (octyl 3-methylbutanoate)	0200	N	
Nonyl isovalerate (nonyl 3-methylbutanoate)	0201	N	
3-Hexenyl 3-methylbutanoate	0202	N	
2-Methylpropyl 3-methylbutyrate (2-methylpropyl 3-methylbutanoate)	0203	N	
2-Methylbutyl 3-methylbutanoate	0204	N, T	No safety concern
Methyl 2-methylbutyrate (methyl 2-methylbutanoate)	0205	N	
Ethyl 2-methylbutyrate (ethyl 2-methylbutanoate)	0206	N	
<i>n</i> -Butyl 2-methylbutyrate (butyl 2-methylbutanoate)	0207	N	
Hexyl 2-methylbutanoate	0208	N	
Octyl 2-methylbutyrate (octyl 2-methylbutanoate)	0209	N	
Isopropyl 2-methylbutyrate (1-methylethyl 2-methylbutanoate)	0210	N, T	
3-Hexenyl 2-methylbutanoate	0211	N, T	
2-Methylbutyl 2-methylbutyrate (2-methylbutyl 2-methylbutanoate)	0212	N	
Methyl 2-methylpentanoate	0213	N, T	
Ethyl 2-methylpentanoate	0214	N	
Ethyl 3-methylpentanoate	0215	N, T	
Methyl 4-methylvalerate	0216	N	

Substance ^a	No.	Specifications ^b	Conclusion based on current levels of intake
Esters of aliphatic acyclic primary alcohols with aliphatic linear saturated carboxylic acids			
Propyl formate	0117	N	No safety concern
Butyl formate	0118	N	
<i>n</i> -Amyl formate (pentyl formate)	0119	N	
Hexyl formate	0120	N	
Heptyl formate	0121	N, T	
Octyl formate	0122	N	
<i>cis</i> -3-Hexenyl formate (<i>cis</i> -3-hexenyl-1-yl formate)	0123	N	
Isobutyl formate (2-methylpropyl formate)	0124	N	
Methyl acetate	0125	N	
Propyl acetate	0126	N	
Butyl acetate	0127	R	
Hexyl acetate	0128	N	
Heptyl acetate	0129	N	
Octyl acetate	0130	N	
Nonyl acetate	0131	N	
Decyl acetate	0132	N	
Lauryl acetate (dodecyl acetate)	0133	N	
<i>cis</i> -3-Hexenyl acetate (<i>cis</i> -3-hexenyl-1-yl acetate)	0134	N	Not evaluated ^c
<i>trans</i> -3-Heptenyl acetate (<i>trans</i> -3-heptenyl-1-yl acetate)	0135	N	
10-Undecen-1-yl acetate	0136	N	
Isobutyl acetate (2-methylpropyl acetate)	0137	N	
2-Methylbutyl acetate (2-methyl-1-butyl acetate)	0138	N	
2-Ethylbutyl acetate	0140	N, T	
Methyl propionate (methyl propanoate)	0141	N	
Propyl propionate (<i>n</i> -propyl propanoate)	0142	N	
Butyl propionate (butyl propanoate)	0143	N	
Hexyl propionate (<i>n</i> -hexyl propanoate)	0144	N	
Octyl propionate (octyl propanoate)	0145	N	
Decyl propionate (decyl propanoate)	0146	N	
<i>cis</i> -3- and <i>trans</i> -2-Hexenyl propionate (<i>cis</i> -3- and <i>trans</i> -2-hexenyl propanoate)	0147	N	
Isobutyl propionate (2-methylpropyl propanoate)	0148	N	
Methyl butyrate (methyl butanoate)	0149	N	No safety concern
Propyl butyrate (<i>n</i> -propyl butanoate)	0150	N	
Butyl butyrate (<i>n</i> -butyl <i>n</i> -butanoate)	0151	N	
<i>n</i> -Amyl butyrate (pentyl butanoate)	0152	N	
Hexyl butyrate (hexyl butanoate)	0153	N	
Heptyl butyrate (heptyl butanoate)	0154	N, T	
Octyl butyrate (octyl butanoate)	0155	N, T	
Decyl butyrate (decyl butanoate)	0156	N, T	
<i>cis</i> -3-Hexenyl butyrate (<i>cis</i> -3-hexen-1-yl butanoate)	0157	N	
Isobutyl butyrate (2-methylpropyl butanoate)	0158	N	
Methyl valerate (methyl pentanoate)	0159	N	
Butyl valerate (butyl pentanoate)	0160	N	
Propyl hexanoate	0161	N	
Butyl hexanoate	0162	N	
<i>n</i> -Amyl hexanoate (pentyl hexanoate)	0163	N	
Hexyl hexanoate	0164	N	
<i>cis</i> -3-Hexenyl hexanoate (<i>cis</i> -3-hexen-1-yl hexanoate)	0165	N, T	

Substance ^a	No.	Specifications ^b	Conclusion based on current levels of intake
Isobutyl hexanoate (2-methylpropyl hexanoate)	0166	N	No safety concern
Methyl heptanoate	0167	N	
Propyl heptanoate	0168	N, T	
Butyl heptanoate	0169	N, T	
<i>n</i> -Amyl heptanoate (pentyl heptanoate)	0170	N	
Octyl heptanoate	0171	N, T	
Isobutyl heptanoate (2-methylpropyl heptanoate)	0172	N, T	
Methyl octanoate	0173	N	
<i>n</i> -Amyl octanoate (pentyl octanoate)	0174	N	
Hexyl octanoate	0175	N	
Heptyl octanoate	0176	N, T	
Octyl octanoate	0177	N, T	
Nonyl octanoate	0178	N, T	
Methyl nonanoate	0179	N	
Methyl laurate (methyl dodecanoate)	0180	N	
Butyl laurate (butyl dodecanoate)	0181	N	
Isoamyl laurate (3-methylbutyl dodecanoate)	0182	N, T	
Methyl myristate (methyl <i>n</i> -tetradecanoate)	0183	N	
Butyl stearate (butyl octadecanoate)	0184	N, T	

Esters derived from branched-chain terpenoid alcohols and aliphatic acyclic carboxylic acids

Citronellyl formate (3,7-dimethyl-6-octen-1-yl formate)	0053	N	No safety concern
Geranyl formate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl formate)	0054	N	
Neryl formate (<i>cis</i> -3,7-dimethyl-2,6-octadien-1-yl formate)	0055	N	
Rhodinyl formate (3,7-dimethyl-7-octen-1-yl formate)	0056	N	
Citronellyl acetate (3,7-dimethyl-6-octen-1-yl acetate)	0057	N	
Geranyl acetate ^c (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl acetate)	0058	R	
Neryl acetate (<i>cis</i> -3,7-dimethyl-2,6-octadien-1-yl acetate)	0059	N	
Rhodinyl acetate (3,7-dimethyl-7-octen-1-yl acetate)	0060	N	
Citronellyl propionate (3,7-dimethyl-6-octen-1-yl propanoate)	0061	N	
Geranyl propionate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl propanoate)	0062	N	
Neryl propionate (<i>cis</i> -3,7-dimethyl-2,6-octadien-1-yl propanoate)	0063	N	
Rhodinyl propionate (3,7-dimethyl-7-octen-1-yl propanoate)	0064	N, T	
Citronellyl butyrate (3,7-dimethyl-6-octen-1-yl butanoate)	0065	N	
Geranyl butyrate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl butanoate)	0066	N	
Neryl butyrate (<i>cis</i> -3,7-dimethyl-2,6-octadien-1-yl butanoate)	0067	N	

Substance ^a	No.	Specifications ^b	Conclusion based on current levels of intake
Rhodinyl butyrate (3,7-dimethyl-7-octen-1-yl butanoate)	0068	N	No safety concern
Citronellyl valerate (3,7-dimethyl-6-octen-1-yl pentanoate)	0069	N, T	
Geranyl hexanoate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl hexanoate)	0070	N, T	
Citronellyl isobutyrate (3,7-dimethyl-6-octen-1-yl 2-methyl propanoate)	0071	N	
Geranyl isobutyrate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl 2-methyl propanoate)	0072	N, T	
Neryl isobutyrate (<i>cis</i> -3,7-dimethyl-2,6-octadien-1-yl 2-methyl propanoate)	0073	N	
Rhodinyl isobutyrate (3,7-dimethyl-7-octen-1-yl 2-methyl propanoate)	0074	N, T	
Geranyl isovalerate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl 3-methyl butanoate)	0075	N, T	
Neryl isovalerate (<i>cis</i> -3,7-dimethyl-2,6-octadien-1-yl 2-methyl butanoate)	0076	N	
Rhodinyl isovalerate (3,7-dimethyl-7-octen-1-yl 3-methylbutanoate)	0077	N, T	
Geranyl 2-ethylbutanoate (<i>trans</i> -3,7-dimethyl-2,6-octadien-1-yl 2-ethylbutanoate)	0078	N, T	

^a The substance names are given as they appear in the specifications monograph (FAO Food and Nutrition Paper, No. 52, Add. 5, 1997). In cases where substances were evaluated under their trivial name, the systematic name is given in parentheses.

^b N, new specifications prepared; NR, specifications not reviewed; R, existing specifications revised; S, specifications exist, revision not considered or not required; T, the existing, new or revised specifications are tentative and comments are invited.

^c The ADI for this substance was maintained.

^d Evaluation postponed, pending consideration of other α,β -unsaturated compounds.

^e Evaluation postponed, pending consideration of other α,β -unsaturated carbonyl compounds.

Contaminant	Toxicological recommendations
Aflatoxins	Potencies were estimated

^a The substance names are given as they appear in the specifications monograph (FAO Food and Nutrition Paper, No. 52, Add. 5, 1997). In cases where substances were evaluated under their trivial name, the systematic name is given in parentheses.

^b N, new specifications prepared; R, existing specifications revised; S, specifications exist, revision not considered or not required; T, the existing, new or revised specifications are tentative and comments are invited; W, existing specifications withdrawn.

^c The existing tentative specifications for carthamus red were revised and the "tentative" designation was maintained. The Committee requested information on the content of carthamin and method of assay.

^d New specifications for enzyme-hydrolysed sodium carboxymethyl cellulose were prepared and designated as "tentative". The Committee requested information on the physical state of the substance as manufactured, the nature and proportion of material of low relative molecular mass present, and tests that distinguish it from sodium carboxymethyl cellulose.

^e The existing tentative specifications for petroleum jelly were revised and the "tentative" designation was maintained. The Committee requested information on the method of analysis and levels of viscosity at 100°C, carbon number at 5% distillation point, average relative molecular mass and oil content. Unless this information was received by 31 March 1998, the specifications would be withdrawn.

^f The specifications for propionic acid used as a preservative and an antimould and antirope agent were revised and designated as "tentative". The Committee requested information on the method of analysis and levels of readily oxidizable substances.

^g The Committee compared the specifications for "diacetyltartaric and fatty acid esters of glycerol" (DATEM) with the existing tentative specifications for "tartaric, acetic and fatty acid esters of glycerol, mixed" and noted that the two substances appear very similar. The Committee has not received information which would allow these substances to be distinguished analytically. It therefore decided to maintain the tentative status of the existing specifications for "tartaric, acetic and fatty acid esters of glycerol, mixed" and requested data that would distinguish this substance from DATEM. Unless such data were provided by 31 March 1998, the Committee would consider combining the specifications for the two substances.

8. **UV Spectra:** No significant absorbance between 290 and 700 nm; molar absorption coefficient is below the benchmark ($1000 \text{ L mol}^{-1} \bullet \text{ cm}^{-1}$)
9. **Appearance/Organoleptic:** Colorless liquid. Warm, powerfully herbaceous, sweet, tobacco-like, coumarinic type odor. Sweet, powerful, warm-herbaceous, coumarin-caramel taste (Arctander, 1969)

3. Volume of use (Worldwide band)

1. **Volume of Use (Worldwide Band):** 1–10 metric tons per year (IFRA, 2015)

4. Exposure to fragrance ingredient (Crete RIFM aggregate exposure model v3.1.2)

1. **95th Percentile Concentration in Fine Fragrance:** 0.013% (RIFM, 2018)
2. **Inhalation Exposure*:** 0.00013 mg/kg/day or 0.0092 mg/day (RIFM, 2018)
3. **Total Systemic Exposure**:** 0.00058 mg/kg/day (RIFM, 2018)

*95th percentile calculated exposure derived from concentration survey data in the Crete RIFM Aggregate Exposure Model (Comiskey, 2015; Safford et al., 2015; Safford et al., 2017; Comiskey et al., 2017).

**95th percentile calculated exposure; assumes 100% absorption unless modified by dermal absorption data as reported in Section V. It is derived from concentration survey data in the Crete RIFM Aggregate Exposure Model and includes exposure via dermal, oral, and inhalation routes whenever the fragrance ingredient is used in products that include these routes of exposure (Comiskey, 2015; Safford et al., 2015; Safford et al., 2017; Comiskey et al., 2017).

5. Derivation of systemic absorption

1. **Dermal:** Assumed 100%
2. **Oral:** Assumed 100%
3. **Inhalation:** Assumed 100%

6. Computational toxicology evaluation

6.1. Cramer Classification: class II, low* (expert judgment)

Expert Judgment	Toxtree v3.1	OECD QSAR Toolbox v4.2
II	II	III

*See the Appendix below for further details.

6.2. Analogs selected

- a. **Genotoxicity:** γ -Valerolactone (CAS # 108-29-2)
- b. **Repeated Dose Toxicity:** None
- c. **Reproductive Toxicity:** None
- d. **Skin Sensitization:** 4-Hydroxybutanoic acid lactone (CAS # 96-48-0)
- e. **Phototoxicity/Photoallergenicity:** None
- f. **Local Respiratory Toxicity:** None
- g. **Environmental Toxicity:** None

6.3. Read-across justification

See Appendix below.

7. Metabolism

No relevant data available for inclusion in this safety assessment.

Additional References: None.

8. Natural occurrence

γ -Hexalactone is reported to occur in the following foods by the VCF*:

Acerola (Malpighia)	Passion fruit (<i>Passiflora</i> species)
Apricot (<i>Prunus armeniaca</i> L.)	Peach (<i>Prunus persica</i> L.)
Mangifera species	Raspberry, blackberry, and boysenberry
Milk and milk products	Rice cake
Nectarine	Tea

*VCF (Volatile Compounds in Food): Database/Nijssen, L.M.; Ingen-Visscher, C. A. van; Donders, J.J.H. (eds). – Version 15.1 – Zeist (The Netherlands): TNO Triskelion, 1963–2014. A continually updated database containing information on published volatile compounds that have been found in natural (processed) food products. Includes FEMA GRAS and EU-Flavis data. This is a partial list.

9. Reach dossier

Available; accessed 10/14/21 (ECHA, 2019).

10. Conclusion

The existing information supports the use of this material as described in this safety assessment.

11. Summary

11.1. Human health endpoint summaries

11.1.1. Genotoxicity

Based on the current existing data, γ -hexalactone does not present a concern for genotoxicity.

11.1.1.1. Risk assessment. γ -Hexalactone was assessed in the Blue-Screen assay and found negative for both cytotoxicity (positive: <80% relative cell density) and genotoxicity, with and without metabolic activation (RIFM, 2013). BlueScreen is a human cell-based assay for measuring the genotoxicity and cytotoxicity of chemical compounds and mixtures. Additional assays on an equi-reactive read-across material were considered to fully assess the potential mutagenic or clastogenic effects of the target material.

There are no studies assessing the mutagenic and clastogenic activity of γ -hexalactone; however, read-across can be made to γ -valerolactone (CAS # 108-29-2; see Section VI).

The mutagenic activity of γ -valerolactone has been evaluated in a bacterial reverse mutation assay conducted in compliance with GLP regulations and in accordance with OECD TG 471 using the standard plate incorporation method. *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, and *Escherichia coli* strain WP2uvrA were treated with γ -valerolactone in dimethyl sulfoxide (DMSO) at concentrations up to 5000 $\mu\text{g}/\text{plate}$. No increases in the mean number of revertant colonies were observed at any tested concentration in the presence or absence of S9 (RIFM, 2017a). Under the conditions of the study, γ -valerolactone was not mutagenic in the Ames test, and this can be extended to γ -hexalactone.

The clastogenic activity of γ -valerolactone was evaluated in an *in vitro* micronucleus test conducted in compliance with GLP regulations and in accordance with OECD TG 487. Human peripheral blood lymphocytes were treated with γ -valerolactone in DMSO at concentrations up to 1001 $\mu\text{g}/\text{mL}$ in the presence and absence of metabolic activation (S9) for 3 h and in the absence of metabolic activation for 24 h. γ -Valerolactone did not induce binucleated cells with micronuclei when tested up to the maximum allowed concentration in either non-activated or S9-activated test systems (RIFM, 2017b). Under the conditions of the study, γ -valerolactone was considered to be non-clastogenic in the *in*

vitro micronucleus test, and this can be extended to gamma-hexalactone.

Based on the data available, γ -valerolactone does not present a concern for genotoxic potential, and this can be extended to gamma-hexalactone.

Additional References: None.

Literature Search and Risk Assessment Completed On: 10/02/20.

11.1.2. Repeated dose toxicity

There are insufficient repeated dose toxicity data on γ -hexalactone or any read-across materials. The total systemic exposure to γ -hexalactone is below the TTC for the repeated dose toxicity endpoint of a Cramer Class II material at the current level of use.

11.1.2.1. Risk assessment. There are no repeated dose toxicity data on γ -hexalactone or any read-across materials that can be used to support the repeated dose toxicity endpoint. The total systemic exposure (0.58 $\mu\text{g/kg/day}$) is below the TTC for γ -hexalactone (9 $\mu\text{g/kg/day}$; Kroes et al., 2007).

Additional References: None.

Literature Search and Risk Assessment Completed On: 08/06/20.

11.1.3. Reproductive toxicity

The MOE for γ -hexalactone is adequate for the developmental toxicity endpoint at the current level of use.

There are insufficient fertility data on γ -hexalactone or on any read-across materials. The total systemic exposure to γ -hexalactone is below the TTC for the fertility endpoint of a Cramer Class II material at the current level of use.

11.1.3.1. Risk assessment. In a developmental toxicity study (GLP and OECD 414-compliant) performed on Crl:CD (Sprague Dawley) IGS BR rats (25/sex/dose), γ -hexalactone was administered through oral gavage at dose levels of 0 (vehicle control: deionized water), 100, 300, or 1000 mg/kg/day for a period of 14 days during gestation from days 6–19. No treatment-related changes were reported for dams in clinical signs, body weights, gravid uterine weight, feed consumption, and necropsy examination. A significant decrease in fetal body weight was reported in the high-dose group; however, the decrease in body weight was within the historical control range. At 300 mg/kg/day, external malformations, including meningocele, were reported in 1 fetus; visceral malformations, including a malpositioned descending aorta, were reported in another fetus; and a skeletal malformation (a vertebral centra anomaly; the right half of lumbar centrum number 2 was absent, and the right half of lumbar centrum number 1 was malpositioned) was reported in 1 fetus. However, these changes were reported in only 3 of 365 fetuses examined at this dose level and were not present at any other dose level. Other soft tissues and skeletal malformations and variants were reported in a single fetus, but they did not occur in a dose-related manner. In addition, the skeletal variants reported in all treated groups were within the historical control data and, therefore, not considered to be treatment-related. A conservative NOAEL for developmental toxicity was considered to be 300 mg/kg/day, based on a significant decrease in fetal body weight at 1000 mg/kg/day (ECHA, 2013).

Therefore, the γ -hexalactone MOE for the developmental toxicity endpoint can be calculated by dividing the γ -hexalactone NOAEL in mg/kg/day by the total systemic exposure to γ -hexalactone, 300/0.00058, or 517241.

In addition, the total systemic exposure to γ -hexalactone (0.58 $\mu\text{g/kg/day}$) is below the TTC (9 $\mu\text{g/kg/day}$; Kroes et al., 2007; Laufersweiler et al., 2012) for the developmental toxicity endpoint of a Cramer Class II material at the current level of use.

There are insufficient fertility data on γ -hexalactone or on any read-across materials that can be used to support the reproductive toxicity

endpoint. The total systemic exposure to γ -hexalactone (0.58 $\mu\text{g/kg/day}$) is below the TTC (9 $\mu\text{g/kg/day}$; Kroes et al., 2007; Laufersweiler et al., 2012) for the fertility endpoint of a Cramer Class II material at the current level of use.

Additional References: None.

Literature Search and Risk Assessment Completed On: 10/01/20.

11.1.4. Skin sensitization

Based on the existing data and read-across 4-hydroxybutanoic acid lactone (CAS # 96-48-0), γ -hexalactone presents no concern for skin sensitization under the current, declared levels of use.

11.1.4.1. Risk assessment. Limited skin sensitization studies are available for γ -hexalactone. Based on the existing data and read-across material 4-hydroxybutanoic acid lactone (CAS # 96-48-0; see Section VI), γ -hexalactone is not considered a skin sensitizer. The chemical structure of these materials indicate that they would not be expected to react with skin proteins directly (Roberts et al., 2007; ToxTree v3.1.0; OECD Toolbox v4.2). In a murine local lymph node assay (LLNA), read-across material 4-hydroxybutanoic acid lactone was not found to be sensitizing when tested up to 100% (ECHA, 2011). In a guinea pig maximization test, γ -hexalactone did not present reactions indicative of sensitization (RIFM, 1977). In 2 human maximization tests, no skin sensitization reactions were observed with γ -hexalactone at 12% (8280 $\mu\text{g/cm}^2$) in petrolatum (RIFM, 1977).

Based on the weight of evidence (WoE) from structural analysis, animal and human studies, and read-across material 4-hydroxybutanoic acid lactone, γ -hexalactone does not present a concern for skin sensitization under the current, declared levels of use.

Additional References: None.

Literature Search and Risk Assessment Completed On: 09/02/20.

11.1.5. Phototoxicity/photoallergenicity

Based on the available UV/Vis spectra, γ -hexalactone would not be expected to present a concern for phototoxicity or photoallergenicity.

11.1.5.1. Risk assessment. There are no phototoxicity studies available for γ -hexalactone in experimental models. UV/Vis absorption spectra indicate no significant absorption between 290 and 700 nm. The corresponding molar absorption coefficient is below the benchmark of concern for phototoxicity and photoallergenicity (Henry et al., 2009). Based on the lack of absorbance, γ -hexalactone does not present a concern for phototoxicity or photoallergenicity.

11.1.5.2. UV spectra analysis. UV/Vis absorption spectra (OECD TG 101) were obtained. The spectra indicate no significant absorbance in the range of 290–700 nm. The molar absorption coefficient is below the benchmark of concern for phototoxic effects, 1000 $\text{L mol}^{-1} \cdot \text{cm}^{-1}$ (Henry et al., 2009).

Additional References: None.

Literature Search and Risk Assessment Completed On: 09/01/20.

11.1.6. Local respiratory toxicity

The MOE could not be calculated due to a lack of appropriate data. The exposure level for γ -Hexalactone is below the Cramer Class III* TTC value for inhalation exposure local effects.

11.1.6.1. Risk assessment. There are no inhalation data available on γ -hexalactone. Based on the Creme RIFM Model, the inhalation exposure is 0.0092 mg/day. This exposure is 51.1 times lower than the Cramer Class III* TTC value of 0.47 mg/day (based on human lung weight of 650 g; Carthew et al., 2009); therefore, the exposure at the current level

of use is deemed safe.

*As per Carthew et al., 2009, Cramer Class II materials default to Cramer Class III for the local respiratory toxicity endpoint.

Additional References: None.

Literature Search and Risk Assessment Completed On: 09/16/20.

11.2. Environmental endpoint summary

11.2.1. Screening-level assessment

A screening-level risk assessment of γ -hexalactone was performed following the RIFM Environmental Framework (Salvito, 2002), which provides 3 tiered levels of screening for aquatic risk. In Tier 1, only the material's regional VoU, its log K_{OW} , and its molecular weight are needed to estimate a conservative risk quotient (RQ), expressed as the ratio Predicted Environmental Concentration/Predicted No Effect Concentration (PEC/PNEC). A general QSAR with a high uncertainty factor applied is used to predict fish toxicity, as discussed in Salvito et al. (2002). In Tier 2, the RQ is refined by applying a lower uncertainty factor to the PNEC using the ECOSAR model (US EPA, 2012b), which provides chemical class-specific ecotoxicity estimates. Finally, if necessary, Tier 3 is conducted using measured biodegradation and ecotoxicity data to refine the RQ, thus allowing for lower PNEC uncertainty factors. The data for calculating the PEC and PNEC for this safety assessment are provided in the table below. For the PEC, the range from the most recent IFRA Volume of Use Survey is reviewed. The PEC is then calculated using the actual regional tonnage, not the extremes of the range. Following the RIFM Environmental Framework, γ -hexalactone was identified as a fragrance material with no potential to present a possible risk to the aquatic environment (i.e., its screening-level PEC/PNEC <1).

A screening-level hazard assessment using EPI Suite v4.11 (US EPA, 2012a) did not identify γ -hexalactone as possibly persistent or bioaccumulative based on its structure and physical-chemical properties. This screening-level hazard assessment considers the potential for a material to be persistent and bioaccumulative and toxic, or very persistent and very bioaccumulative as defined in the Criteria Document (Api, 2015). As noted in the Criteria Document, the screening criteria applied are the same as those used in the EU for REACH (ECHA, 2012). For persistence, if the EPI Suite model BIOWIN 3 predicts a value < 2.2 and either BIOWIN 2 or BIOWIN 6 predicts a value < 0.5, then the material is considered potentially persistent. A material would be considered potentially bioaccumulative if the EPI Suite model BCFBAF predicts a fish BCF ≥ 2000 L/kg. Ecotoxicity is determined in the above screening-level risk assessment. If, based on these model outputs (Step 1), additional assessment is required, a WoE-based review is then performed (Step 2). This review considers available data on the material's physical-chemical properties, environmental fate (e.g., OECD Guideline biodegradation studies or die-away studies), fish bioaccumulation, and higher-tier model outputs (e.g., US EPA's BIOWIN and BCFBAF found in EPI Suite v4.11).

11.2.2. Risk assessment

Based on the current Volume of Use (2015), γ -hexalactone presents no risk to the aquatic compartment in the screening-level assessment.

11.2.2.1. Key studies. Biodegradation:

No data available.

Ecotoxicity:

No data available.

Other available data

γ -Hexalactone has been registered for REACH with the following additional data available at this time (ECHA, 2019):

The *Daphnia magna* acute immobilization test was conducted according to the OECD 202 guideline. The 48-h EC50 value based on nominal test concentration was reported to be 3.176 mg/L (95% CI:

2.478–4.001 mg/L).

The algae growth inhibition test was conducted according to the OECD 201 guideline. The 72-h EC50 value for biomass was reported to be 13.06 mg/L.

11.2.3. Risk assessment refinement

Ecotoxicological data and PNEC derivation (all endpoints reported in mg/L; PNECs in μ g/L).

Endpoints used to calculate PNEC are underlined.

Exposure information and PEC calculation (following RIFM Environmental Framework: Salvito et al., 2002).

Exposure	Europe (EU)	North America (NA)
Log K_{OW} Used	0.6	0.6
Biodegradation Factor Used	0	0
Dilution Factor	3	3
Regional Volume of Use Tonnage Band	1–10	1–10
Risk Characterization: PEC/PNEC	<1	<1

Based on available data, the RQ for this material is < 1. No further assessment is necessary.

The RIFM PNEC is 2.544 μ g/L. The revised PEC/PNECs for EU and NA are not applicable. The material was cleared at the screening-level; therefore, it does not present a risk to the aquatic environment at the current reported volumes of use.

Literature Search and Risk Assessment Completed On: 09/15/20.

Appendix

Read-across Justification

Methods

The read-across analogs were identified using RIFM fragrance chemicals inventory clustering and read-across search criteria (RIFM, 2020). These criteria are in compliance with the strategy for structuring and reporting a read-across prediction of toxicity as described in Schultz et al. (2015) and are consistent with the guidance provided by OECD within Integrated Approaches for Testing and Assessment (OECD, 2015) and the European Chemical Agency read-across assessment framework (ECHA, 2017).

- First, materials were clustered based on their structural similarity. Second, data availability and data quality on the selected cluster were examined. Third, appropriate read-across analogs from the cluster were confirmed by expert judgment.
- Tanimoto structure similarity scores were calculated using FCFC4 fingerprints (Rogers and Hahn, 2010).
- The physical–chemical properties of the target material and the read-across analogs were calculated using EPI Suite v4.11 (US EPA, 2012a).
- J_{\max} values were calculated using RIFM's Skin Absorption Model (SAM). The parameters were calculated using the consensus model (Shen et al., 2014).
- DNA binding, mutagenicity, genotoxicity alerts, oncologic classification, ER binding, and repeat dose categorization predictions were generated using OECD QSAR Toolbox v4.2 (OECD, 2018).
- Developmental toxicity was predicted using CAESAR v2.1.7 (Cassano et al., 2010).
- Protein binding was predicted using OECD QSAR Toolbox v4.2 (OECD, 2018), and skin sensitization was predicted using Toxtree.
- The major metabolites for the target material and read-across analogs were determined and evaluated using OECD QSAR Toolbox v4.2 (OECD, 2018).
- To keep continuity and compatibility with *in silico* alerts, OECD QSAR Toolbox v4.2 was selected as the alert system.

	Target Material	Read-across Material	Read-across Material

Summary

There are insufficient toxicity data on γ -hexalactone (CAS # 695-06-7). Hence, *in silico* evaluation was conducted to determine read-across analogs for this material. Based on structural similarity, reactivity, physical–chemical properties, and expert judgment, γ -valerolactone (CAS # 108-29-2) and 4-hydroxybutanoic acid lactone (CAS # 96-48-0) were identified as read-across analogs with sufficient data for toxicological evaluation.

Conclusions

- γ -Valerolactone (CAS # 108-29-2) was used as a read-across analog for the target material, γ -hexalactone (CAS # 695-06-7), for the genotoxicity endpoint.
- The target material and the read-across analog belong to the class of lactones.
- The key difference between the target material and the read-across analog is that target has an ethyl substituent at the fifth position, whereas the read-across analog has a methyl substituent at the fifth position on the carboxylic end. This structural difference is toxicologically insignificant.
- The similarity between the target material and the read-across analog is indicated by the Tanimoto score. Differences between the structures that affect the Tanimoto score are toxicologically insignificant.
- The physical–chemical properties of the target material and the read-across analog are sufficiently similar to enable a comparison of their toxicological properties.
- According to the OECD QSAR Toolbox v4.2, structural alerts for toxicological endpoints are consistent between the target material and the read-across analog.
- There is an “AN2|AN2 >> Michael-type addition on α,β-unsaturated carbonyl compounds|AN2 >> Michael-type addition on α,β-unsaturated carbonyl compounds >> Four- and Five-Membered Lactones|SN2|SN2 >> Alkylation, ring-opening SN2 reaction|SN2 >> Alkylation, ring-opening SN2 reaction >> 4- and 5-Membered Lactones” (DNA Binding [OASIS v1.4, QSAR Toolbox v4.2]) alert for both the target and the read-across analog. This is a typical structural alert for 4- or 5-membered lactones. It is believed that the mechanism of action for 5-membered lactones is associated with the presence of the α -methylidene group (α -methylene- γ -butyrolactones) in some Ames-active representatives of this class, which gives rise to the α , β -conjugated system. It has been suggested that the presence of the α -methylene- γ -lactone structural fragment is of

critical importance for toxicity, but the exact mechanism has not been elucidated. The facility for Michael-type addition with the exocyclic α -methylene group on γ -lactone is also suggested to determine the biological activity. The absence of the α -methylidene group in both the target material and read-across analog suggests that both materials do not pose any genotoxic concern, and hence, the alerts are superseded.

- The target material and the read-across analog are expected to be metabolized similarly, as shown by the metabolism simulator.
- The structural alerts for the endpoints evaluated are consistent between the metabolites of the read-across analog and the target material.
- 4-Hydroxybutanoic acid lactone (CAS # 96-48-0) was used as a read-across analog for the target material, γ -hexalactone (CAS # 695-06-7), for the skin sensitization endpoint.
- The target material and the read-across analog belong to the class of aliphatic esters.
- The key difference between the target material and the read-across analog is that target has a propyl substituent on the alcohol end, whereas the read-across analog has a hexyl substituent on the alcohol end. This structural difference is toxicologically insignificant.
- The similarity between the target material and the read-across analog is indicated by the Tanimoto score. Differences between the structures that affect the Tanimoto score are toxicologically insignificant.
- The physical–chemical properties of the target material and the read-across analog are sufficiently similar to enable a comparison of their toxicological properties.
- According to the OECD QSAR Toolbox v4.2, structural alerts for toxicological endpoints are consistent between the target material and the read-across analog.
- There is “Acylation|Acylation \gg Direct Acylation Involving a Leaving group|Acylation \gg Direct Acylation Involving a Leaving group \gg Acetates” (Protein Binding (OECD)) alert for both the target material and read-across analog. This alert arises due to the presence of an acyl functionality in both the target material and read-across analog. However, based on the existing data and read-across 4-hydroxybutanoic acid lactone (CAS # 96-48-0), γ -hexalactone presents no concern for skin sensitization under the current, declared levels of use.
- The target material and the read-across analog are expected to be metabolized similarly, as shown by the metabolism simulator.
- The structural alerts for the endpoints evaluated are consistent between the metabolites of the read-across analog and the target material.

Explanation of Cramer Classification

1N,2N,3N,5N,6N,7Y,8Y,9N,20Y,21N,18Y.

Due to potential discrepancies with the current *in silico* tools (Bhatia et al., 2015), the Cramer Class of the target material was determined using expert judgment based on the Cramer decision tree (Cramer et al., 1978).

- Q1. A normal constituent of the body? No.
 Q2. Contains functional groups associated with enhanced toxicity? No.
 Q3. Contains elements other than C, H, O, N, and divalent S? No.
 Q5. Simply branched aliphatic hydrocarbon or a common carbohydrate? No.
 Q6. Benzene derivative with certain substituents? No.
 Q7. Heterocyclic? No.
 Q8. Lactone or cyclic diester? Yes.
 Q9. Lactone, fused to another ring, or 5- or 6-membered α,β -unsaturated lactone? No.
 Q20. Aliphatic with some functional groups (see Cramer et al., 1978 for detailed explanation)? No.
 Q21. Three or more different functional groups? No.
 Q18. One of the list? (see Cramer et al., 1978 for a detailed explanation on the list of categories). No. Class II (Class intermediate)

SECTION 2: Hazards identification

· **2.1 Classification of the substance or mixture**

· **Classification according to Regulation (EC) No 1272/2008**

The substance is not classified, according to the CLP regulation.

· **2.2 Label elements**

· **Labelling according to Regulation (EC) No 1272/2008** Void

· **Hazard pictograms** Void

· **Signal word** Void

· **Hazard statements** Void

· **2.3 Other hazards**

· **Results of PBT and vPvB assessment**

· **PBT:** Not applicable.

· **vPvB:** Not applicable.

Safety data sheet

according to 1907/2006/EC, Article 31

Printing date 05.01.2024

Version number 1

Revision: 05.01.2024

Trade name: *y*-Hexanolactone [CAS:695-06-7] (SB52220)

(Contd. of page 1)

SECTION 3: Composition/information on ingredients

- **3.1 Substances**
- **CAS No. Description**
695-06-7 gamma-Hexalactone

SECTION 4: First aid measures

- **4.1 Description of first aid measures**
- **General information:** No special measures required.
- **After inhalation:** Supply fresh air; consult doctor in case of complaints.
- **After skin contact:** Generally the product does not irritate the skin.
- **After eye contact:** Rinse opened eye for several minutes under running water.
- **After swallowing:** If symptoms persist consult doctor.
- **4.2 Most important symptoms and effects, both acute and delayed** No further relevant information available.
- **4.3 Indication of any immediate medical attention and special treatment needed**
No further relevant information available.

SECTION 5: Firefighting measures

- **5.1 Extinguishing media**
- **Suitable extinguishing agents:**
CO₂, powder or water spray. Fight larger fires with water spray or alcohol resistant foam.
- **5.2 Special hazards arising from the substance or mixture** No further relevant information available.
- **5.3 Advice for firefighters**
- **Protective equipment:** No special measures required.

SECTION 6: Accidental release measures

- **6.1 Personal precautions, protective equipment and emergency procedures** Not required.
- **6.2 Environmental precautions:**
Dilute with plenty of water.
Do not allow to enter sewers/ surface or ground water.
- **6.3 Methods and material for containment and cleaning up:**
Absorb with liquid-binding material (sand, diatomite, acid binders, universal binders, sawdust).
- **6.4 Reference to other sections**
See Section 7 for information on safe handling.
See Section 8 for information on personal protection equipment.
See Section 13 for disposal information.

SECTION 7: Handling and storage

- **7.1 Precautions for safe handling** No special measures required.
- **Information about fire - and explosion protection:** No special measures required.
- **7.2 Conditions for safe storage, including any incompatibilities**
- **Storage:**
- **Requirements to be met by storerooms and receptacles:** No special requirements.
- **Information about storage in one common storage facility:** Not required.
- **Further information about storage conditions:** None.
- **7.3 Specific end use(s)** No further relevant information available.

SECTION 8: Exposure controls/personal protection

- **8.1 Control parameters**
- **Ingredients with limit values that require monitoring at the workplace:** Not required.
- **Additional information:** The lists valid during the making were used as basis.
- **8.2 Exposure controls**
- **Appropriate engineering controls** No further data; see section 7.
- **Individual protection measures, such as personal protective equipment**
- **General protective and hygienic measures:**
The usual precautionary measures are to be adhered to when handling chemicals.
- **Respiratory protection:** Not required.
- **Hand protection**
The glove material has to be impermeable and resistant to the product/ the substance/ the preparation.
Due to missing tests no recommendation to the glove material can be given for the product/ the preparation/ the chemical mixture.
Selection of the glove material on consideration of the penetration times, rates of diffusion and the degradation
- **Material of gloves**
The selection of the suitable gloves does not only depend on the material, but also on further marks of quality and varies from manufacturer to manufacturer.
- **Penetration time of glove material**
The exact break through time has to be found out by the manufacturer of the protective gloves and has to be observed.
- **Eyeface protection** Goggles recommended during refilling

SECTION 9: Physical and chemical properties

- **9.1 Information on basic physical and chemical properties**
- **General Information**
- **Physical state** Fluid
- **Colour:** Not determined.
- **Odour:** Characteristic
- **Odour threshold:** Not determined.
- **Melting point/freezing point:** Undetermined.
- **Boiling point or initial boiling point and boiling range** 219 °C (695-06-7 gamma-Hexalactone)
- **Flammability** Not applicable.
- **Lower and upper explosion limit**
- **Lower:** Not determined.
- **Upper:** Not determined.
- **Flash point:** 98 °C (695-06-7 gamma-Hexalactone)
- **Decomposition temperature:** Not determined.
- **pH** Not determined.
- **Viscosity:**
- **Kinematic viscosity** Not determined.
- **Dynamic:** Not determined.
- **Solubility**
- **water:** Fully miscible.
- **Partition coefficient n-octanol/water (log value)** Not determined.
- **Vapour pressure:** Not determined.
- **Density and/or relative density**
- **Density at 20 °C:** 1.023 g/cm³
- **Relative density** Not determined.
- **Vapour density** Not determined.

- **Corrosive to metals** Void
- **Desensitised explosives** Void

SECTION 10: Stability and reactivity

- **10.1 Reactivity** No further relevant information available.
- **10.2 Chemical stability**
- **Thermal decomposition / conditions to be avoided:** No decomposition if used according to specifications.
- **10.3 Possibility of hazardous reactions** No dangerous reactions known.
- **10.4 Conditions to avoid** No further relevant information available.
- **10.5 Incompatible materials:** No further relevant information available.
- **10.6 Hazardous decomposition products:** No dangerous decomposition products known.

SECTION 11: Toxicological information

- **11.1 Information on hazard classes as defined in Regulation (EC) No 1272/2008**
- **Acute toxicity** Based on available data, the classification criteria are not met.
- **Skin corrosion/irritation** Based on available data, the classification criteria are not met.
- **Serious eye damage/irritation** Based on available data, the classification criteria are not met.
- **Respiratory or skin sensitisation** Based on available data, the classification criteria are not met.
- **Germ cell mutagenicity** Based on available data, the classification criteria are not met.
- **Carcinogenicity** Based on available data, the classification criteria are not met.
- **Reproductive toxicity** Based on available data, the classification criteria are not met.
- **STOT-single exposure** Based on available data, the classification criteria are not met.
- **STOT-repeated exposure** Based on available data, the classification criteria are not met.
- **Aspiration hazard** Based on available data, the classification criteria are not met.

(Contd. on page 5)

Safety data sheet
according to 1907/2006/EC, Article 31

Printing date 05.01.2024

Version number 1

Revision: 05.01.2024

Trade name: *y*-Hexanolactone [CAS:695-06-7] (SB52220)

(Contd. of page 4)

· **11.2 Information on other hazards**· **Endocrine disrupting properties**

Substance is not listed.

SECTION 12: Ecological information· **12.1 Toxicity**· **Aquatic toxicity:** No further relevant information available.· **12.2 Persistence and degradability** No further relevant information available.· **12.3 Bioaccumulative potential** No further relevant information available.· **12.4 Mobility in soil** No further relevant information available.· **12.5 Results of PBT and vPvB assessment**· **PBT:** Not applicable.· **vPvB:** Not applicable.· **12.6 Endocrine disrupting properties**

The product does not contain substances with endocrine disrupting properties.

· **12.7 Other adverse effects**· **Additional ecological information:**· **General notes:**

Water hazard class 2 (German Regulation) (Assessment by list): hazardous for water

Do not allow product to reach ground water, water course or sewage system.

Danger to drinking water if even small quantities leak into the ground.

SECTION 13: Disposal considerations· **13.1 Waste treatment methods**· **Recommendation** Smaller quantities can be disposed of with household waste.· **Uncleaned packaging:**· **Recommendation:** Disposal must be made according to official regulations.· **Recommended cleansing agents:** Water, if necessary together with cleansing agents.**SECTION 14: Transport information**· **14.1 UN number or ID number**· **ADR, IMDG, IATA**

Void

· **14.2 UN proper shipping name**· **ADR, IMDG, IATA**

Void

· **14.3 Transport hazard class(es)**· **ADR, ADN, IMDG, IATA**· **Class**

Void

· **14.4 Packing group**· **ADR, IMDG, IATA**

Void

· **14.5 Environmental hazards:**

Not applicable.

· **14.6 Special precautions for user**

Not applicable.

· **14.7 Maritime transport in bulk according to IMO instruments**

Not applicable.

· **UN "Model Regulation":**

Void

EU

Safety data sheet

according to 1907/2006/EC, Article 31

Printing date 05.01.2024

Version number 1

Revision: 05.01.2024

Trade name: *y*-Hexanolactone [CAS:695-06-7] (SB52220)

(Contd. of page 5)

SECTION 15: Regulatory information

- **15.1 Safety, health and environmental regulations/legislation specific for the substance or mixture**
- **Labelling according to Regulation (EC) No 1272/2008** Void
- **Hazard pictograms** Void
- **Signal word** Void
- **Hazard statements** Void
- **Directive 2012/18/EU**
- **Named dangerous substances - ANNEX I** Substance is not listed.

· **LIST OF SUBSTANCES SUBJECT TO AUTHORISATION (ANNEX XIV)**

Substance is not listed.

· **DIRECTIVE 2011/65/EU on the restriction of the use of certain hazardous substances in electrical and electronic equipment – Annex II**

Substance is not listed.

· **REGULATION (EU) 2019/1148**

· **Annex I - RESTRICTED EXPLOSIVES PRECURSORS (Upper limit value for the purpose of licensing under Article 5(3))**

Substance is not listed.

· **Annex II - REPORTABLE EXPLOSIVES PRECURSORS**

Substance is not listed.

· **Regulation (EC) No 273/2004 on drug precursors**

Substance is not listed.

· **Regulation (EC) No 111/2005 laying down rules for the monitoring of trade between the Community and third countries in drug precursors**

Substance is not listed.

· **National regulations:**

· **Other regulations, limitations and prohibitive regulations**

· **Substances of very high concern (SVHC) according to REACH, Article 57**

Substance is not listed.

· **15.2 Chemical safety assessment:** A Chemical Safety Assessment has not been carried out.

SECTION 16: Other information

This information is based on our present knowledge. However, this shall not constitute a guarantee for any specific product features and shall not establish a legally valid contractual relationship.

This Safety Data Sheet is in compliance with Regulation (EC) No 1907/2006, Article 31 as amended by Regulation (EU) 2020/878.

· **Department issuing SDS:** Product safety department

· **Contact:** Mrs. Taralova

· **Abbreviations and acronyms:**

ADR: Accord relatif au transport international des marchandises dangereuses par route (European Agreement Concerning the International Carriage of Dangerous Goods by Road)

IMDG: International Maritime Code for Dangerous Goods

IATA: International Air Transport Association

GHS: Globally Harmonised System of Classification and Labelling of Chemicals

CAS: Chemical Abstracts Service (division of the American Chemical Society)

PBT: Persistent, Bioaccumulative and Toxic

SVHC: Substances of Very High Concern

vPvB: very Persistent and very Bioaccumulative
